the greater scheme conceived much earlier, aimed at an understanding of arthropod phylogeny. She had extended and completed a draft of the late O. W. Tiegs on *The Evolution of the Arthropoda* and had discovered that much basic information was just not available. In 1960 she retired from her Readership at Kings and from then on enjoyed the hospitality of the British Museum (Natural History) as Honorary Research Associate and was also a Research Fellow of Queen Mary College. Freed from teaching she felt able to seek the information for herself, beginning with a major examination of the structure and function of the mandible which was published in a wonderfully illustrated paper of over 200 pages between parts 7 and 8 of the locomotion series. She was becoming increasingly impressed by the mutual exclusiveness of the engineering designs between and even within classes. She considered these designs to have evolved in response to different habits which persisted for long periods and that each lineage represented an independent attainment of the arthropod grade of organisation.

About this time she was cruelly afflicted by an arthritic condition, yet she had enjoyed lunch-time tennis on the BM court until she was well over 60. At the Myriapod Congress in Manchester in 1972 she was relatively mobile because of an ingenious mechanical aid for one leg designed and constructed by herself and husband. Looking down a microscope at an exhibit, she drew for me an accurate picture of the cataract which limited her field to a narrow jagged annulus. Cataracts were removed one by one and hip and wrist joints were extensively re-modelled. During this difficult period she wrote *The Arthropoda*, recently published by Oxford University Press, a masterly summary of her 50 years research into their habits, functional morphology and evolution, running to 527 pages and lavishly illustrated by 186 text figures. She corrected the proofs in hospital after one of her operations. During the last two years she had compiled four chapters of a new general text on arthropods, written and presented a paper to a symposium on the evolution of the major arthropod groups at Hull, contributed a review to a book on arthropod phylogeny and undergone a second pelvic joint operation. The strain was too great.

The arthropods were not the only animals in her life. Her home and garden housed a veritable menagerie of birds and mammals which she cared for each day. Over a period of 21 years she developed the long haired Colourpoint cats with such delightful tem-

peraments and exported kittens to all points of the globe. The history of her Mingchui cats is recounted in her book *Colourpoint, Longhair and Himalayan Cats* (1971). This work ran parallel to her arthropod studies and brought her world-wide acclaim from an entirely different public. All this while at the centre of a delightful household, cooking superb meals, a delightful person with a lively conversation and an understanding smile. She will be sorely missed by her husband, Dr J. P. Harding and her two children, Elizabeth and Martyn

J. Gordon Blower

E. R. Creed

EDWIN ROBERT CREED died on 28 November 1978, aged 42, after an illness of three months. His parents were both physiologists, his father being a Fellow of New College, Oxford, also of Winchester. Robert was among that group of boys from Marlborough School who, from the 1920s onwards, became distinguished as biologists.

Like his father, he went to Trinity College, Oxford. After graduating in zoology he remained in the department to carry out research in ecological genetics. It gained for him the PhD Degree, also a Research Fellowship at New College. When this expired in 1970 under a time-limit, he became Lecturer, and later Senior Lecturer, in Zoology at University College, Cardiff, where he was in charge of genetics.

Unlike many scientists and scholars in general, Robert Creed did not find his period of National Service a disastrous waste of time. Among other things, it enabled him to develop his ability in engineering. Indeed, he retained what to some of us seemed an astonishing capacity to interchange and adjust the parts of old motor cars, of which he always had several. Moreover, for the rest of his life he took an active interest in the Territorial Army Volunteer Reserve.

His marriage to Elizabeth Hilton was a source of great happiness. He leaves two daughters, one aged 7 and the other 4 years. He liked to live in fairly large houses plentifully supplied with cats.

He was a good lecturer, but his outstanding educational achievement was as a demonstrator in practical classes. Here he excelled. He would take great care to arrange interesting exhibits and experiments. It was his habit to take away and work up the class results, and he would subsequently explain in what ways they had proved rewarding or unusual.

He was also a successful research worker. In order to investigate the ecological genetics of the butterfly *Maniola jurtina* he once camped with me on an uninhabited island in the Isles of Scilly, and he repeatedly joined our research group studying that insect in the south-west of England. He had a flair for such work, in which his observations were accurate and often revealing; and on these occasions his light-hearted energy was an asset and an encouragement.

His own researches were in particular directed to the polymorphism of the two-spot ladybeetle, *Adalia bipunctata*. This is typically scarlet with a black spot on each wing-cover; but two black forms with, respectively, four and six red spots are also known, all three types being controlled as multiple alleles. Creed showed that the black phases are industrial melanics, the only known instance of that condition in a species protected from predation by a powerfully unpleasant scent and taste: one practising, therefore, the aposematic way of life.

Creed and his colleagues also found that the black phases of *A. bipunctata* are favoured when pollution results from coal of high volatility, not of low volatility as in South Wales; nor does the presence of sulphur dioxide in the atmosphere encourage their spread, as in some moths. Moreover, the two black forms respectively survive better when the fuel is, or is not, subject strongly to caking. This work, described in his published articles, is a valuable contribution to our knowledge of adaptation to industrial conditions.

In spite of his youthful appearance, Robert Creed had a highly developed critical faculty and his comments when the draft of an article was submitted to him were of penetrating value. He was a Conservative in politics, original in research, devoted in friendship. His early death is a tragic loss of one who can ill be spared.

E. B. Ford

Lord Cranbrook

THE death of John David, 4th Earl of Cranbrook on 22 November 1978 deprives many natural history and scientific societies of a skilful adviser and an enthusiastic and knowledgeable colleague.

His multifarious activities in public service and in support of East Anglian naturalists' organisations have been acclaimed elsewhere (*The Times*, 24 November 1978) but it is for his capacities as a scientist of no mean distinction and as a staunch member and officer of national biological societies that we, on behalf of the

Linnean Society of London and of the Mammal Society, would wish him to be remembered. We have no doubt that other societies, such as the Zoological Society of London, would wholeheartedly support this tribute.

Lord Cranbrook's schooling as a naturalist with a world-wide field of interest began in the Far East in association with such pioneers as Kingdon Ward. Thereafter he was deeply committed to the furtherance of field biological studies in Great Britain.

For over 46 years he laboured on behalf of our oldest biological society, the Linnean Society of London, which has always acted as a fruitful meeting ground for amateurs (of which he was an outstanding example) and professionals. He served on its Council for 14 years and was Treasurer for 12 years. His astute business sense, combined with his robust common sense, proved invaluable to the Society during its special appeal for funds in 1969. As a result of this appeal, the Linnean Society was able to rehouse and adequately curate its unique collections of plants and animals on which Linnaeus once worked; a service which was appreciated by scientists throughout the world.

Lord Cranbrook's enthusiasm, energy and eminence among his wide contacts put him in a unique position to foster progress. Nobody appealed to him in vain for advice and it was always given widely, humorously and forcibly.

Compared with the Linnean, the Mammal Society is a relative newcomer with no valuable collections to house and curate. Lord Cranbrook was a founder member in 1954 and, as its assiduous President, guided the Society in its formative years. It was rare for him to miss a council meeting and each year, when he presided over the Annual General Meeting, there was keen speculation as to whether he could cut ten minutes off his previous record for its speedy completion. Nevertheless, there was no skimping and his grasp of essentials, together with his succinct exposition, gave every point due consideration.

As a Trustee of the British Museum (Natural History) between 1963 and 1973, he again provided a valuable link between the naturalists at large and the more circumscribed specialists.

Lord Cranbrook was a valued speaker in the House of Lords: valued especially because of the reliability of his 'homework' and the clarity and force with which he dealt with complex and controversial matters. All naturalists must be grateful for his pilotage during recent years, when he faced increasing disability with great courage, of the Conservation of Wild Creatures and Wild Plants Act 1975.

He contributed numerous publications to scientific journals, of which the most outstanding was his study of a population of noctule bats which came to feed on crickets at a local rubbish dump. Capturing and marking them with the aid of mist-nets was a notable achievement at that time (1965, *Proc. zool. Soc. Lond.* **144**: 1-24).

Lord Cranbrook's cheerful presence and leadership will be sorely missed throughout the ranks of naturalists and biologists.

P. H. Greenwood
H. N. Southern

Jean Clark Dan

JEAN CLARK DAN died of asthma in Tateyama, Japan on 13 November 1978, at age 68. Born and reared in a staunchly Presbyterian family in Westfield, New Jersey, USA, she graduated from Wilson College (1932), and continued study under L. V. Heilbrunn at the University of Pennsylvania and in summer at the Marine Biological Laboratory, Woods Hole. On obtaining her PhD (1936) she married Katsuma Dan who had also received his PhD (1934) with Heilbrunn. They proceeded to Japan via Europe with a stay at the Stazione Zoologica of Naples. Eventually they settled in Tokyo but their early years included long periods at the Misaki Marine Biological Station of Tokyo University.

The Dans produced five children, whose upbringing overlapped World War II. Jean had to move away from home territory but adapted cheerfully, and despite many hardships the whole family managed to survive. Then she undertook multifarious enterprises to surmount postwar adversity: one negotiation utilized army garbage for village rehabilitation while preserving self-respect all around. And she doggedly struggled back to the scientific world.

In 1947 she revisited Woods Hole (to which she would often again return as to another home) where peacetime activities had been re-established. With help from the American Philosophical Society she took a phase contrast microscope back to Japan where, under the wing of Tokyo Metropolitan University, she set up at Misaki a research program on fertilization of marine invertebrates. Publication soon followed. The papers became increasingly important. Her first two 'Studies on the Acrosome' (1952, 1954) demonstrated how the tip of the spermatozoon changes under various conditions, and introduced the term

acrosome reaction. She was a pioneer in examining such material with the electron microscope. Some workers were slow to accept her findings but her mounting evidence, together with that of others, firmly established that the reaction does indeed occur. There followed many other important papers. She explored the sperm lysin problem. Much of her later observation and speculation centered around 'dynamic morphology' (precursors, triggers, etc.) of membranous and other parts of the region she came to call the *acrosomal complex*.

She won grants and fellowships from sources in both countries, received her Japanese PhD, was given the award (1958) of the Zoological Society of Japan, and found herself in international demand for lectures and conferences on spermatology and fertilization. She was on the editorial board of *Development, Growth and Differentiation*.

Jean was appointed Lecturer (1959), then Professor (1973) at Ochanomizu University where she taught and supervised graduate students. Interested in that University's Tateyama Marine Biological Station from its inception, she became Director (1975), and planned to spend much of her time at Tateyama after retiring from the University (1976).

During the war Jean had come to speak fluent Japanese. As Japanese biologists returned to research and writing many sought her help with English usage. For years she devotedly helped transform their texts into English suitable for publication. She translated into English Osada's *Children of the A-Bomb* (1959, with R. Sieben-Morgen), and *Invertebrate Embryology* (1968, eds. M. Kumé and K. Dan). Moreover, she assisted in the English translation of publications of His Majesty, Emperor Hirohito.

The above barely suggests the warm vital Jean Dan. She was a strong swimmer, walked well, liked to gather wild mushrooms or buy a warm sweet-potato from a street vendor. She liked having a dog. Her children enjoyed a whole family of Siamese cats. In her laboratory would be a flower in a beaker, an attractive picture on the wall. She enthusiastically espoused causes as great as world peace, and with equal vigor would propel a specific student into opportunities for advanced study. Jean was seldom at a loss for words; also, her penchant for friendly listening to and advising others knew no barrier in age, sex or nationality, discipline or problem.

She will be missed as a scientist—and as a person.

Laura Hunter Colwin
Arthur L. Colwin

Indispensable New Titles from *HUMANA*

Introduction to Bioinstrumentation with Biological, Environmental, and Medical Applications

by **Clifford D. Ferris**
University of Wyoming

Here is an outstanding practical text on contemporary analog instrumentation. The author guides the reader through the fundamental principles of instrument design, thoroughly treating both linear and non-linear systems, and reviews the nature and behavior of the major components of instrumentation. A volume of *Contemporary Instrumentation and Analysis*. Dec. 1978; 352pp., approx. 120 illus.

"... I wish to convey my enthusiasm about the book ... written from the standpoint of a beginner in the field of instrumentation theory it presents the material logically and in an understandable way ... the treatment is widely applicable and should find an eager audience not only among individuals using bioinstrumentation, but also among chemists, psychologists, physicists, and engineers."

Gary M. Hieftje, Indiana University

Hardcover edition: ISBN 0-89603-000-8, \$29.50

Softcover student edition: ISBN 0-89603-003-2, \$14.50

Handbook of Environmental Engineering Volume 1

Air and Noise Pollution Control

edited by **Lawrence K. Wang**
Stevens Institute of Technology
and **Norman C. Pereira**
Olin Corporation

The **Handbook of Environmental Engineering** is a major new work designed to provide comprehensive treatment not only of the scientific principles underlying highly useful pollution abatement systems, but also of their practical application in the control and improvement of environmental quality.

In this first of the five planned parts of the Handbook, an array of distinguished authors offer thorough tutorial accounts of the fundamental physical and engineering principles, methods, processes, and operations especially applicable to air and noise pollution control problems. Among the important topics specifically treated are: Electrostatic Precipitation; Atmospheric Dilution; Fabric Filtration; Noise Control Methodology; Cyclones; Wet Scrubbing.

The **Handbook of Environmental Engineering** will prove an indispensable resource for all engineers, students, and managers concerned with understanding and effectively solving problems of pollution abatement. March 1979; 512 pp., approx. 70 illus.
ISBN 0-89693-001-6; \$49.50

Medical Information Systems

The Laboratory Module

by **Ralph R. Grams**
University of Florida College of Medicine

Are you planning soon to install a sophisticated new hospital laboratory information system? Or are you perhaps looking for ways to improve on or supplement an existing computerized laboratory facility? Whatever the nature of your concerns, Ralph R. Grams' exceptionally practical new book will prove invaluable by fully describing in down-to-earth detail the design, installation, personnel interfacing, contracting specifics, and ultimately the highly successful integration of such a system into a busy hospital environment. March, 1979; 448 pp; 154 figures and charts.

ISBN 0-89603-004-0; \$39.50

Contemporary Issues in Biomedical Ethics

edited by **John W. Davis**, **Barry Hoffmaster**,
and **Sarah Shorten**
University of Western Ontario, Canada
with a FOREWORD by **Daniel Callahan**

"Should medicine's goal be to forestall death, to relieve suffering, or simply to maintain health? Does the principle of the 'dignity of life' or 'the right to life' require that medicine always strive to keep people alive to the bitter end?' These and many other humanly urgent questions are discussed and debated in **CONTEMPORARY ISSUES IN BIOMEDICAL ETHICS**. Stimulating and insightful essays by the following distinguished contributors are included: John Ladd, Robert Audi, Richard T. Hull, Michael D. Bayles, Joseph Ellin, Lisa H. Newton, Colleen D. Clements, Bernard M. Dickens, Dan W. Brock, Glen C. Graber, Arthur J. Dyck, M. Josephine Flaherty, David J. Roy. A volume of *Contemporary Issues in Biomedicine, Ethics, and Society*. February 1979, 336pp.

ISBN: 0-89603-002-4; \$19.50.

Pesticides

Contemporary Roles in Agriculture, Energy, and the Environment

edited by **T. J. Sheets**
North Carolina State University
and **David Pimentel**
Cornell University

In this significant new book a distinguished group of scientists has brought to bear a broad spectrum of interdisciplinary expertise on many of the crucial issues associated with contemporary pesticide usage. Their insightful articles review such major elements of the new strategies of integrated pest control as pesticide-increased agricultural production; socioeconomics of pesticides; environmental effects of pesticides; energy and pesticides; pesticide use cost/benefit ratios; human health and pesticides. A volume of *Contemporary Issues in Science and Society*. March 1979; 208 pp.

ISBN 0-89603-005-9; \$19.50.

Solar Energy

Chemical Conversion and Storage

edited by **Rinh R. Hautala**, **R. Bruce King**,
and **Charles Kutal**
University of Georgia

Chemical approaches to solar energy conversion and storage are undergoing very rapid and already productive exploration. In the present volume, many forefront investigators offer in-depth coverage of the principal concepts and most recent advances through the area, including solar cells; photosynthesis as an energy source; photochemical production of hydrogen; nitrogen photoreduction; photogalvanic and photovoltaic power generation; petroleum planations. Essential reading for all those actively involved in this fascinating and crucial new discipline. A volume of *Contemporary Issues in Science and Society*. April 1979; approx. 400 pp.

ISBN: 0-89603-006-7; \$34.50.

ELSEVIER/NORTH-HOLLAND BIOMEDICAL PRESS

Developments in Biochemistry

Developments in Biochemistry is a new series of books derived from papers and invited lectures presented at specialized conferences covering important areas of biochemistry. Each book is published within months of the conference to insure the currency and availability of the material to the scientific community.

Volume 5

Cytochrome Oxidase

Proceedings of the Japanese - American Seminar on Cytochrome Oxidase held in Osaka, Japan on 29th - 2nd September 1978

edited by **Tsoo E. King, Utaki Orii, Britton Chance and Kazuo Okuni.**

1979 x + 416 pages US\$ 61.00/Dfl.125.00
ISBN 0-444-80100-6

The first book to be devoted exclusively to cytochrome oxidase that will be of invaluable assistance to all molecular biologists, biophysicists and membranologists working in the field.

Volume 4

The Chemistry and Biology Pteridines

Invited papers of the VIth International Symposium on the Chemistry and Biology of Pteridines held at La Jolla, California on the 25th - 28th September 1978

edited by **R.L. Kisluk and G.M. Brown.**

1979 704 pages US\$40.00/Dfl.82.00
ISBN 0-444-00305-3

Chemists, biologists and biochemists will appreciate this volume for the valuable material it contains on today's pteridine research goals and practices.

Volume 3

Physical Aspects of Protein Interactions

Proceedings of the Conference on Physical Aspects of Protein Interactions, held in Miami, Florida, U.S.A., on the 12th - 13th September 1978

edited by **Nicholas N. Catsimopoulos.**

1978 300 pages US\$35.00/Dfl.71.50
ISBN 0-444-00304-5

A major new work shedding light on the physical aspects of subunit, protein-ligand, and protein-protein interactions as exemplified in specific biological problems or in generally useful models.

Volume 2

Electrophoresis '78

Proceedings of the International Conference of Electrophoresis, Massachusetts Institute of Technology, Cambridge, Massachusetts, April 19-21, 1978

edited by **Nicholas N. Catsimopoulos.**

1978 456 pages US\$52.00/Dfl.106.50
ISBN 0-444-00294-4

Offers valuable insights into new applications of electrophoresis for a wide range of methodologies.

Two Major New Journals

Journal of Biochemical and Biophysical Methods

A Journal both for specialists interested in method development and researchers looking for new methods to solve biological, biochemical, biophysical and medical research problems.

Managing Editor: C.F. CHIGNELL, *Research Triangle Park, NC, U.S.A.* Associate Managing Editor: S. HJERTEN, *Uppsala, Sweden.*

1979 Volume 1 in 6 issues Subscription Price: US\$75.50/Dfl.155.00 including postage.

Photobiochemistry and Photobiophysics

an interdisciplinary journal for the rapid publication of concise papers on all aspects of photochemistry and photobiophysics.

Managing Editor: H. Metzner, *Tübingen, West Germany.*

1979 Volume 1 in 6 issues US\$75.50/Dfl.155.00 including postage.

FASEB exhibition news

THE Federation of American Societies for Experimental Biology hold their 63rd Annual Meeting, FASEB79, in the Dallas Convention Center between April 1 and April 10. Products of interest to the experimental biologist will be shown at the accompanying exhibition. For more details on products mentioned in this FASEB exhibition news section circle the appropriate numbers on the reader enquiry card bound inside the cover.

Bio-Rad Laboratories

NEW from Bio-Rad is the Quanta-Count II B-12 assay which is sensitive to vitamin B-12 alone, and does not react with its analogues. The test was developed in response to evidence (*New Engl. J. Med.*, 12 October 1978) that most commercial assays for B-12 in serum will give apparently normal values in 10 to 20% of anaemic patients. These discrepancies are attributed to the presence of biologically inactive B-12 analogues in human serum. The analogues bind with non-specific 'R' protein binders contained in most commercial preparations of intrinsic factor, and are measured as true vitamin B-12. Unlike intrinsic factor, which binds only metabolically active B-12, the ubiquitous R proteins cannot distinguish between B-12 and the analogues. In the new system from Bio-Rad the intrinsic factor preparation is treated to eliminate the R protein binding activity. Bio-Rad use the principles of two-site immunoradiometric assay (IRMA) in the new Quantimmune HTSH thyrotropin assay.

Circle No. 99 on Reader Enquiry Card.

Brinkmann Instruments

FROM Brinkmann Instruments Inc. comes a new plant/laboratory safety device that carefully monitors temperature limits and/or liquid-levels. The Brinkmann Excess Temperature and Liquid-Level Safety Alarm Model R-35 will prevent operation of an instrument above a pre-set critical temperature and prevent low liquid-level operation.

The Brinkman R-35 safety alarm which monitors temperature limits and/or liquid level

It can be used in a variety of instruments (rated at 15 A or less) such as constant temperature circulators, water baths, freezers, ovens and reaction vessels. It is particularly useful for monitoring overnight operations. The desired maximum temperature limit can be easily set at any point between 0° and 350°C. Temperature is monitored through a platinum resistance probe, while liquid-level is monitored through a float switch attached to the platinum probe. If the pre-set temperature limit is reached due to overheating, or, if the liquid-level becomes too low, the R-35 will automatically shut off power to the system and produce a loud, audible warning signal. Power will remain off until the fault has been corrected and a reset button engaged.

Circle No. 98 on Reader Enquiry Card.

Accurate Chemical & Scientific Corporation

IDENTIFICATION of DNP-amino acids, phenols, lipoxinone, flavonoids, vitamins, antibiotics etc, on thin-layer chromatograms is made simpler by the ready-to-use Cheng-Chin polyamide layer sheets. Cheng-Chin sheets are available from Accurate Chemical & Scientific Corporation who also provide a bibliography listing papers on TLC work on a wide variety of compounds. Reprints of an article by K.-T. Wang and B. Weinstein on the technique of TLC on polyamide layers are also available.

Circle No. 97 on Reader Enquiry Card.

Sauter

THE K Series of electronic precision balances from August Sauter offer high precision coupled with large capacity. K Series balances all feature two weighing ranges; for example the K 1200 weighs to 120 g with 0.01 g resolution or to 1,200 g with 0.1 g resolution. Results are presented in less than a second on the digital display. The balances are equipped with a tare facility which operates at the press of a key. The analog coarse display gives a continuous reading of the total weight on the balance and both analog and digital outputs can be put through connections to printers or other processors. The problems involved in weighing experimental animals can be minimised by using the DI 309 integrator. The integrator automatically computes the average of a pre-set number of weighings and displays the average on a digital readout. For mice, rats, guinea pigs and for animals as large as rabbits, dogs and monkeys there are balances suitable in the Sauter range. The DI 309, shown here in use with a K 1200 balance, can also

Two radioassays from Bio-Rad. Left, the Quanta-Count II assay for vitamin B-12 and right, the Quantimmune assay for human TSH

The Santer DI 309 integrator and K 1200 balance

be connected to a printer. The Sauter RT Series of balances includes the RT 200 with 200 g capacity and 1 mg resolution and the RT 1200 with 1,200 g capacity and 0.1 g resolution. Both are fitted with a BCD signal so can be used in a data processing application. Sauter produce the MR 401 printing calculator which will display measured weights and also carry out direct calculations on them. The calculator is capable of the four basic arithmetic operations, automatic percentage calculation and storage of intermediate and final totals. **Circle No. 96 on Reader Enquiry Card.**

BDH

AN addition to the BDH range of molecular weight markers is now available. The marker mixture (Product 44247) contains markers of MW values between 2,512 and 16,949. Also new is BDH Product 44168. This new reagent 1-(*m*-nitrobenzyloxy) methylpyridinium-chloride (NBPC), is used in the preparation of aminobenzyloxymethyl paper to facilitate the detection of specific RNA bands (Alwine, J. C. *et al. Proc. natn. Acad. Sci. U.S.A.* **74**, 5350-5354, 1977). BDH products are available in the USA from Gallard-Schlesinger Chemicals.

Circle No. 95 on Reader Enquiry Card.

Buchler

A NEW temperature-regulated water bath with a mating lift assembly has been introduced by Buchler. The Thermo-Lift can be used in a variety of common laboratory procedures requiring the application of heat to a stationary apparatus. Bath temperatures can be maintained at any point in the ambient to 80 °C temperature range as indicated by an integrally mounted dial thermometer. A sturdy scissor-type jack safely raises or lowers the bath throughout the range of 7.5–16.5 ins. Additionally, the bath and lift assembly may be separated to

Buchler's Thermo-Lift waterbath

function as independent units. The large (6×9 ins) base of the lift assembly provides stable support for the bath or any other accessory. Heating is by a 550 W stainless steel immersion heater controlled by a differential expansion thermal sensor. This sensor, with a sensitivity of ± 0.2 °C, maintains the 3-l bath volume within 2 °C of average throughout. Stainless steel and anodised aluminium construction protect the unit from corrosion.

NEW FROM MILES RESEARCH PRODUCTS

REAGENTS FOR IMMUNOHISTOCHEMICAL TECHNIQUES

The constant search for the visualization of specific antigenic substances in cells and tissues has resulted in the development of a number of techniques to accomplish this task. Miles Research Products now supplements our already extensive line of reagents for immunohistochemical techniques with the following products:

FLUORESCEIN CONJUGATED ANTISERA

Liquid Antisera To:	Produced In:	Code No.
Bovine IgG ₁ (Specific To Subclass)	Rabbit	64-177
Bovine IgG ₂ (Specific To Subclass)	Rabbit	64-178
Bovine IgA (Specific To α Chain)	Rabbit	64-260
Bovine IgM (Specific To μ Chain)	Rabbit	64-261
Chicken IgG (H. & L. Chain)	Rabbit	65-196
Human IgG (H. & L. Chain)	Goat	65-207
Rabbit IgG (H. & L. Chain)	Sheep	65-204
Sheep IgG (H. & L. Chain)	Rabbit	65-205

PEROXIDASE CONJUGATED ANTISERA

Liquid Antisera To:	Produced In:	Code No.
Dog IgG (H. & L. Chain)	Rabbit	61-210
Horse IgG (H. & L. Chain)	Rabbit	61-211

INCREDIBLE TWO

Now the Alzet® minipump works up to two weeks.

The first minipump was incredible—up to one week of continuous drug or hormone delivery in the unrestrained rat or mouse.

The credibility of the 1701, 1 μ l/hour minipump is widely recognized; it is the unique, reliable research tool that makes it easy to do the kinds of experiments one could previously only dream about.

Alza now introduces incredible two—the 1702 minipump—up to two weeks of continuous drug or hormone delivery in the unrestrained rat or mouse. Half the pumping rate—0.5 μ l/hour—but twice the duration as the credible 1701.

It is ideal for studies of centrally mediated drug or hormone action or for studies where local microperfusion of drugs or hormones can be used to test for local effects. It is also the tool to consider for steady state tracer studies.

Request technical information from Alza, Dept. Y,
3170 Porter Drive, Palo Alto, California
94304. Phone 415/494-5323.

The C1285 image analysis system from Hamamatsu

system analyses information from images, using a combination of optical, video, and computer hardware to measure, analyse and tabulate height, width, diameter, total area, inner area, outer area, perimeter, per cent area and location of up to several hundred discrete objects in each image. Features such as digital noise reduction, interactive image editing, image storage, and shading correction permit accurate analysis of even difficult images. Operation is as easy as typing on a keyboard or touching a button to request functions or enter operating parameters as the unit requests them. The C1285 is easily interfaced to optical microscopes, macroviewers, film viewers and other optical systems to provide information in a variety of research and quality control applications. An RS232C printer output allows production of hard copy for permanent records.

Sartorius 1201 MP2-BCD

Cedarlane Laboratories

A BROADLY reactive, strongly cytotoxic mouse anti-Ia^k alloantiserum has been introduced by Cedarlane Laboratories. This antiserum is prepared by immunising A.TH mice with lymphocytes derived from A.TL mice. These two strains are congenic, differing at the I region of the H-2 complex but identical at the K and D regions. The H-2 haplotype of A.TH is K^sI^sD^d and that of A.TL is K^sI^kD^d. The antiserum potentially detects the gene products (Ia antigens) of the entire I^k region. In the presence of a suitable source of complement it is cytotoxic to the expected number of A.TL lymphocytes: spleen 50%; lymph node 40%; thymus 5%; bone marrow 15%. This antiserum can be used to quantitate lymphocytes bearing the appropriate Ia antigens or to remove these cells from a population for functional studies.

Prochem

At the FASEB show Prochem are exhibiting their comprehensive catalogue of stable isotopes including carbon 12 and 13, nitrogen 15, oxygen 16, 17 and 18, deuterated compounds, multiply labelled compounds, and labelled gases and mixtures. Of special interest is a new line of 99 atom % carbon-13 intermediates and deuterated amino and fatty acids.

Circle No. 91 on Reader Enquiry Card.

Sartorius

THE new Sartorius fully-automatic electronic analytical top-loading balance, Model 1201 MP2-BCD, offers a weighing range of 30 grams to an accuracy of 0.1mg. This balance does not require dialing-in of weights or arrestment. To operate it, one simply places the sample on the pan and reads the result in just seconds on a large, bright seven-segment digital readout. The Model 1201 MP2-BCD also features: full-range push-button taring, a weighing chamber accessible from three sides and BCD-output permitting interfacing with printers, calculators, etc. For weighing heavier objects the Sartorius 2000 Series of suspended-pan analytical balances offers 0.1 mg readability. The 2003 MP1-BCD Model has a capacity of 166 g and the same features as the 1200 Series. Suitable for use with both 1200 and 2000 Series balances, the A7079 data printer is a low-cost electrostatic printer which allows any number displayed by the digital readout to be printed on tape for a permanent record. At FASEB 79 these Sartorius products are displayed on the Brinkmann Instruments stand.

Advanced Mechanical Technology

A NEW diagnostic instrument called a biomechanics platform has been introduced by Advanced Mechanical Technology Inc. The Model OR6-3 shown measures forces and torques about three orthogonal axes. Forces are measured to 500 lbs with 0.25 lb resolution while torques are read to 4,000 in-lbs with 2.0 in-lbs resolution.

The OR6-3 biomechanics platform

The instrument has many medically oriented applications such as: orthopedics, certain neurological investigations, evaluation of prosthetic devices, athletic performance studies and ballistograms. The platform is characterised by its very high sensitivity, high stiffness and a high natural frequency. Full strain gauge bridges provide operation with a minimum of crosstalk between outputs (less than 3%), the work area is 18.25×20 inches and the unit weighs approximately 60lbs. Maximum suggested excitation level is 10 V per channel. The Model OR6-3 biomechanics platform is available with or without complete instrumentation.

Radiochemical Centre, Amersham

To supplement the supply of iodine-131 solutions used for diagnostic purposes, the Radiochemical Centre offers sodium iodide (^{131} I) solution, B.P. in gelatin capsules, which are available from stock in five nominal activities. The capsules are of the hard gelatin type (size no. 3) containing an inert phosphate carrier into which the iodine-131 is absorbed. The mean activity of capsules from any one batch lies between 90% and 110% of the nominal activity. The coefficient of variation between capsules of the same batch is within 1.4%.

Sienco Inc.

An improved version of the Sienco Dual sample platelet aggregation meter, featuring reduced sample requirements and improved optics is now on the market. With a minimum sample requirement of only 0.2 ml, as well as standard 0.4 ml, the Sienco Model DP-247-E is especially useful for pediatric and other applications where only small samples are available. The Sienco aggregation meter, based on optical transmission through a cuvette, generates two simultaneous curves on a single pen or two pen recorder under identical sample conditions. The dual run capability allows the choice of

HIGHEST STANDARD OF QUALITY IN BIOLOGICAL REAGENTS FOR THE STUDY OF NUCLEIC ACIDS, SYNTHESIS AND PROCESSING.

		PRICES
RIBONUCLEASE PHYL I (Cat. No. ERN-PHY) (RNase I from <i>Physarum Polycephalum</i>) This novel enzyme preferentially digests G, A and U residues allowing discrimination between C and U in RNA sequencing by the gel method	Free from other Ribonuclease and Phosphatase activities	145.00/100 units
T4 POLYNUCLEOTIDE KINASE (Cat. No. EPN-4) (RNase-free) Prepared from T4-infected RNase I ⁺ <i>E. coli</i> , specifically labels 5'-OH termini of RNA and DNA chains. With this product kinase labelling of small quantities of large RNA's for sequencing is possible for the first time	Free of nucleases	75.00/100 units 315.00/500 units
T4 RNA LIGASE (Cat. No. ERL-4) (RNase and DNase-free) The enzyme is capable of adding single residues (in the form of dNp) to 3' termini of the RNA chains allowing sequence analysis by the gel method. Ligase from RNase I ⁺ <i>E. coli</i> allows application of this approach to a variety of large RNA species	Specific Activity 2000 units/mg Completely Free of RNase and DNase Activities	60.00/100 units 235.00/500 units
TERMINAL TRANSFERASE (Cat. No. ETT-C) (from calf thymus) Suitable for addition of polydeoxy-nucleotides to an appropriate primer, or a single addition of a nucleotide at 3' end to create products suitable for DNA sequencing (procedure for a single nucleotide addition is provided by request)	Specific activity 50,000 units/mg Completely free of DNase activity	58.00/500 units 195.00/1000 units
ALKALINE PHOSPHATASE (Cat. No. EAP-1) (from <i>E. coli</i> BL 15 RNase I ⁺) This preparation is free of any detectable RNase or DNase activities	Specific activity 140 units/mg	65.00/100 units 120.00/250 units
DNA POLYMERASE I (Cat. No. EDP-1) (Kornberg polymerase) From <i>E. coli</i> BL 15 For analytical and preparative purposes Suitable for nick translation of DNA in vitro	Specific activity 15000 units/mg Free of DNase and Exonuclease III	155.00/250 units 275.00/500 units
EXONUCLEASE III Cat. No. EEX-III This enzyme digests double-stranded DNA from 3' end and yields single-stranded DNA	Free of endonuclease I or II Not less than 35000 units/mg	60.00/250 units 95.00/500 units

OUR FIBRONECTIN MAKES YOUR CELLS GROW ATTACHED TO CULTURE FLASKS . . . and other growth surfaces.

You have had disappointing results trying to grow cells in culture, we may have the remedy . . . our Human Fibronectin (CR-HFN). This product has repeatedly proven effective in getting fastidious cells to attach to surfaces—and grow.

CR-HFN, — a glycoprotein cell surface antigen* — adsorbs to surfaces to provide a hospitable environment for anchorage-dependent cells. Cells which were previously impossible to culture, now grow. Plating efficiency is dramatically increased. And the variability of plating with different serum batches is reduced or eliminated.

At Collaborative Research, we're committed to the development of products which make tissue culture a dependable science. CR-HFN is the latest addition to our growing line of tissue culture products—including Epidermal Growth Factor, Fibroblast Growth Factor, Nerve Growth Factor, Multiplication Stimulating Activity, Endothelial Cell Growth Supplement, and Human Thrombin.

To find out more about these products and what they can mean for your research, write or call today. Or for immediate delivery of any of these products, phone Customer Service, 617-899-1133.

A dual sample platelet aggregation meter from Sienco

several sample combinations, saves time, and minimises plasma deterioration. An important application for the Sienco aggregation meter is the detection and characterisation of haemostatic disorders associated with haemorrhagic problems (decreased aggregation) and thrombotic tendencies (increased aggregation). The instrument provides excellent aggregation resolution with lipemic plasmas as well as very low platelet count plasmas. In addition to platelet function determinations, the Sienco aggregation meter may also be used to measure plasma coagulation.

Labindustries

THE first non-glass, positive-displacement micropipettor with disposable, plastic, precision tips that can handle any chemical reagent with extreme accuracy and precision, has been announced by Labindustries. These lightweight L/I micropipettors feature a unique one-handed operation, using inexpensive snap-on snap-off plastic, disposable tips, which are precision volumetric transfer micropipets, for sampling and dispensing of all liquids, including serum. Accuracy and reproducibility range from as low as 0.5% at 1,000 μ l to 1.5% at 5 μ l. Eleven fixed-volume models cover the range from 5 to 1,000 μ l. All are colour-coded for ease of identification. These air-free micropipettors aspirate and discharge the entire aliquot without loss or carry-over, since the pipet is internally wiped clean by its Teflon plastic plunger in each operation. A unique feature of the L/I micropipettor is that its calibration rod and adjustment tool are stored in the handle of the instrument where it cannot be lost. Labindustries supplies its chemically resistant plastic tips bulk packaged in quantities of 100, 250, or 1,000, and also in dual purpose boxes of 250, 500, or 1,000 which serve as both snap-on dispensing and snap-off disposal containers without contact with the operator.

Precision Cells Inc.

THE pen-size battery-driven cuvette stirrer from Precision Cells provides good mixing of solutions for all types of cuvettes down to microcell size. Stirring can be accomplished easily even under the most difficult conditions. The Delrin blade ensures that there is a minimum of cross-contamination, and it is shaped to dispel air bubbles in the solution.

Circle No. 83 on Reader Enquiry Card.

The Precision Cells cuvette stirrer

"Knowledge is of two kinds. We know a subject ourselves, or we know where we can find information upon it."

Samuel Johnson from Boswell, *Life of Johnson* (Spring, 1772)

Subject knowledge of the first kind is becoming more and more difficult to possess in the voluminous, ever-expanding world of life science literature. That's where BIOSIS comes in—to help you "know where we can find information upon it."

BIOSIS hasn't been around quite as long as this famous quote, but we've been living up to it for over 50 years. Biosciences Information Service of Biological Abstracts, serving the life science communities, will cover more than 275,000 unique research reports in 1979 in a variety of information services—printed, film and magnetic tapes.

For details, write or call BIOSIS User Services Department, 2100 Arch Street, Philadelphia, Pa. 19103 USA (215) 568-4016 or contact our Official Representative in your area.

Bio-Molecular Dynamics

A NEGATIVE pressure micro protein dialysis concentrator is now available from Bio-Molecular Dynamics. This self-contained system will simultaneously dialyse and concentrate to predetermined quantitative microlitre volumes . . . completely unattended. Nine models, including autoclavable units, are available providing a selection of predetermined, quantitative final volumes from 50 to 1,000 microlitres. **Circle No. 82 on Reader Enquiry Card.**

Savant Instruments Inc.

In their FASEB exhibit Savant features a new evaporator-concentrator. The Speed-Vac, with magnetic drive isolates the upper vacuum chamber from the lower drive section. This instrument is now widely used for the evaporation and concentration of valuable biological solutions. The instrument eliminates bumping and smearing of the sides of the tubes thus eliminating the necessity for washdowns. The sample is always in a high vacuum environment and at near zero temperature to provide the highest protection against the possible deterioration of the sample. A wide variety of culture tubes and micro-centrifuge tubes may be used with a

The Savant Speed-Vac evaporator-concentrator

variety of available rotors. The Speed-Vac evaporator achieves 100% sample recovery and concentration.

Medical Arts

ANIMAL jackets for biomedical research are available from Alice King Chatham. Animal jackets, suits and restraints alleviate animal stress, resulting in more physiological responses. Suits function as surgical protective devices and provide housing for catheters, electrodes, microinfusion pumps, etc. Made of washable nylon net which can be gas sterilised, all items are semi-custom made and are available in standard sizes for dogs, cats, monkeys, rabbits and rats.

Circle No. 80 on Reader Enquiry Card.

An Alice King Chatham animal jacket

Manostat

THE Pistolpet from Manostat is a pistol-like grip pipetting instrument that can be mounted directly to the most commonly used reagent bottles and provides a quick safe method for dispensing all chemicals. The unit has been designed for most dispensing procedures, simply squeeze to dispense . . . release to refill. The 2-inch short travel trigger contributes to better control while reducing wrist and finger fatigue. Because the unit is completely constructed of Teflon and glass, all chemicals can be handled with this new pipettor. The rugged housing is moulded of high impact plastic to withstand hard use. It is particularly useful for dispensing organic solvents for RIA

and scintillation counting work. Pistolpet is available in two capacity ranges 8.5 ml and 20 ml, both with high reproducibility and are reported accurate to $\pm 0.5\%$ of full scale. Also available is a remote attachment that allows dispensing from one and five gallon containers.

Circle No. 79 on Reader Enquiry Card.

The Manostat Pistolpet in use

BioSciences Information Service

THE Biosis Biosystematic Index of *Abstracts of Entomology* reflects the most recent changes in the major taxonomic categories of viruses and bacteria. Subject headings particularly affected by the expanded biosystematic categories include economic entomology epidemiology, virology, insect pathology and physiology, phytopathology and biological control. These permit the retrieval of complete surveys of a more precise host-microbe taxonomic relationship through currently accepted taxonomic systems of the bacteria and viruses.

Newly on the market. For more details about these products circle the appropriate numbers on the reader enquiry card bound inside the cover. These notes are prepared from information provided by the manufacturers.

Electronic balances. Mettler. The new PC range of top loaders from Mettler Instruments is suitable for weighing operations in which both a large weighing range and a high resolution of the measured weight values are needed. It used to take two balances to alternately weigh in light and heavy components, or to weigh small quantities into heavy containers with better than average accuracy. But a single PC balance with Mettler DeltaRange can

A Mettler balance fitted with the Delta Range system

now perform this task much more simply. A 10-times more accurate fine

range—the Mettler DeltaRange—can be recalled anywhere within the overall weighing range as often as needed. Whenever a more accurate readability with one extra decimal place is desired. And this fine range always covers one-tenth of the total weighing range. If the weight of the container exceeds the fine range, the tare weight is automatically indicated with the readability of the coarse range. When the container is tared out, the Mettler DeltaRange is called up at the same time. Weighing now begins at zero with the accuracy of the fine range and continues that way until the limit of the fine range is reached. If the total weight of the various fine weighings exceeds the limit of the fine range, the Mettler DeltaRange can again be recalled by pressing the control bar.

Circle No. 76 on Reader Enquiry Card.

Disposable desiccator plates. Spectrum announce the new disposable blue desiccator plates. They are comprised of a highly porous membrane covering a plate of silica gel. The blue colour slowly changes to a pale pink as the plate absorbs water. The bottom is clear polystyrene, which allows instant visual inspection of drying agent efficacy. It can be regenerated for re-use by heating in an oven, or it can be disposed of.

Circle No. 75 on Reader Enquiry Card.

Disposable scoops and spatulas. Spectrum's new disposable scoops are made of heavy duty polyethylene, and can be used for measuring liquids or solids in laboratory functions. They have an easy grip handle and come in a variety of assorted sizes, packaged in sets of 25. The new disposable spatulas are moulded of chemically resistant polypropylene. They are sealed on one end and cut at an angle on the other, for easy access to use in laboratory bottles. They are heat resistant, virtually unbreakable and economically priced, 100 to a package.

Substrate for alkaline phosphatase testing. J. T. Baker announces the availability of a new, high quality *p*-nitrophenylphosphate disodium salt for alkaline phosphatase testing. The main feature of the substrate is the extremely low inorganic phosphate content which is now guaranteed to be less than 0.1%. J. T. Baker also offers a range of standardised DEA- and AMP buffers.

Circle No. 71 on Reader Enquiry Card.

Laboratory dispensers. Misco. A wide selection of Misco dispensers, which can cope with the requirements of most laboratory dispensing tasks, are now available. Precision manufactured and tested, the flat-top glass dispensers are modular in construction with a periscoping scale post for ease of storage and stacking. All parts which come into contact with liquid are made of borosilicate glass and Teflon. The working parts of the dispenser are contained in the glass bottle. The Misco threaded bottom dispenser, together with adaptors, will fit any glass joint or screw-neck container.

Circle No. 70 on Reader Enquiry Card.

Germinators/Incubators. Harrington Enterprises, has introduced a line of germinator/incubators featuring a fibre-reinforced plastic construction. Both interior and exterior are constructed of structural, highly flame-resistant, glass-reinforced, polyester sandwich panels. This method produces equipment with high strength and light weight, with no shock hazard, no corrosion, and no seams to leak. It is easily cleaned and is double insulated. The germinator/incubators, series I-12G and I-20, are also equipped with sophisticated electronic controllers. A wide range of units with variable parameters of temperature, humidity, light spectrum and intensity are available.

Circle No. 69 on Reader Enquiry Card.

Digital temperature alarm unit. British Rototherm. The Temp-A-Lert digital temperature monitor from BR allows the user to pre-set high and low alarm limits. Designed for medical, industrial and laboratory applications, the Temp-A-Lert gives a visual and/or audible alarm if the temperature goes under or over the predetermined limits. The unit, designated TA986, is a desk top model with dimensions of 81 mm $\times$ 156 mm $\times$ 212 mm, and features a Centigrade to Fahrenheit conversion switch with a large 0.5 in. digital display. Accurate readings can be taken within 10 s in liquids, 45 s in humans and slightly longer in ambient air. The unit is supplied complete with a rechargeable nickel cadmium battery.

Circle No. 68 on Reader Enquiry Card.

Centrifuge. Burkard. Burkard Scientific announce the latest Koolspin table-top centrifuge, the model 2121100. Now with a 25.5-cm bowl, this version of Koolspin has increased capacity, and a swing-out rotor for Universal bottles (25 ml). Many combinations of carrier, tube and bucket are available in addition to the existing rotors, which all fit the new model. Also, a 55° angle rotor has been introduced to accommodate 105-mm long tubes, in two versions, 16 or 18 mm diameter.

Circle No. 67 on Reader Enquiry Card.

Human chorionic gonadotrophin anti-serum. Northeast Biomedical Laboratories announce the introduction of a new antiserum to human chorionic gonadotrophin (β -subunit). This material has been raised in goats and will be supplied as undiluted serum. Five standard preparations and conjugates are available on a routine basis but other conjugates can be made to order for special applications.

Circle No. 66 on Reader Enquiry Card.

An SP3 infrared spectrophotometer from Pye Unicam

IR Spectrophotometers. Pye Unicam. The new SP3 series of infrared spectrophotometers from Pye Unicam offer the performance benefits of a ratio recording system hitherto associated with high cost research type instrumentation. This has been made possible by basing the design on a rapid response pyroelectric detector and a new high energy ceramic source. All three models in the SP3 range are suitable for both qualitative and quantitative studies. The most simple version, the SP3-100 has a frequency range of 4,000 cm^{-1} to 600 cm^{-1} and is designed for applications where rapid sample throughput and quantitative accuracy are essential.

Circle No. 65 on Reader Enquiry Card.

Scanning spectrophotometers. Pye Unicam. Two models have been added to the Pye Unicam SP8 series of UV/visible spectrophotometers. The SP8-250 is a double monochromator version of the SP8-200 microprocessor controlled, research spectrophotometer and the SP8-150 is offered as a higher performing variation of the SP8-100 formula. These four models share with the lower cost SP6 range, the benefits of a major breakthrough in optical technology—master holographic gratings.

Circle No. 64 on Reader Enquiry Card.

High voltage pulse generator. Rofin's 7540 series high voltage pulse generator is intended to operate mainly with infra-red modulator systems such as the Rofin series 7500. The 7540 features various rise times from 1 ns to 70 ns and pulse repetition rates of 10 kHz or 100 kHz depending on the choice of output module. The pulse width is variable from 1 ns to 100 μs at an output of 5 kV p-p. A 3-unit modular design approach provides flexibility and ease of servicing. The 7540 will operate with any electro-optic modulator system or high impedance load. It will drive into load impedances from 200 ohms to many megohms.

An unconventional balance with an extra measure of accuracy

Mettler DeltaRange breaks through the boundaries that used to restrict the capacity/accuracy ratios of conventional weighing instruments. And Mettler PC electronic top-loading balances are equipped with this new *Mettler DeltaRange* feature.

Just press the control bar of the Mettler PC4400, for example, and you get a 400 g fine range with readings that are 10 times as accurate as those in the coarse range. And you can do it as often as you wish, at any point of the entire weighing range. That is to say, whenever and wherever a 0.01 g readability is needed. On a balance that has a capacity of no less than 4000 g!

In practice, this means that you can use a heavy container to accurately weigh in as many components as you want. Or that you can weigh one time on a lightweight paper, the next time into a heavy recipient; both times with results that are readable to the second decimal place.

To learn more about the many things your Mettler PC balance can do for you with outstanding speed and precision, send for our detailed brochure. It's an eye-opener.

How Britain runs its science

This highly successful chart, which appeared in Nature 28 August 1975 (but is still much requested and much referred to), has now been completely revised and updated to include all major changes in the personnel and administration of British science.

Measuring approximately 2' x 3' and containing black-and-white illustrations of prominent figures, copies of this chart are now available at 75p (UK), US \$1.50 (Rest of World).

Payment may be made in any currency at the prevailing exchange rate. Cheques should be made payable to Macmillan Journals Ltd. Prices include postage and packing.

To order please complete the coupon below, or write, enclosing the correct remittance.

Density marker beads for Percoll gradients

Density marker beads. Pharmacia. Pharmacia Fine Chemicals announce the availability of density marker beads, for calibration of density gradients of Percoll. Density marker beads are coloured derivatives of Sephadex, each type specially derivatised to have a specific density in Percoll. The beads are used as an external marker, and the shape of the gradient (either preformed or generated in situ) is monitored simply by measuring the distance between the bands.

Circle No. 62 on Reader Enquiry Card.

Programmable calculator. Sinclair. A new, 79 step programmable calculator, designed for advanced professional use, has been introduced by Sinclair Radionics. The Enterprise Programmable comes complete with a three volume program library, carrying case, high energy alkaline battery and comprehensive instruction manual. The three volume programme library includes 316 ready to use programs covering general finance, mathematics, physics, electronics and engineering calculations. In addition to the program library there is provision to record personal programmes on blank cards. The Enterprise Programmable is based on the Enterprise model, which is a compact, portable or desk top unit, complete with a.c. mains adaptor, and the large, bright 8-digit red display features fully floating decimal point or fixed scientific notation. The Enterprise Programmable has seven independent, three function memories, common and natural logs and antilogs, y^x , sin, cos, tan, arcsin, arccos, arctan and degree/radian conversions. Its full 79-step program facility has merged upper case functions, forward/backward stepping, conditional and unconditional branching.

Circle No. 61 on Reader Enquiry Card.

Scientific calculator. Texas Instruments. A new powerful slimline scientific calculator incorporating statistical functions and a unique Constant Memory feature has been introduced by Texas Instruments. The new TI-50 can retain data in its two full arithmetic memories even when the calculator is switched off, and offers 60

algebraic calculator functions, including logarithms and trigonometry, plus statistical operations. Apart from the two memories with their Constant Memory feature, the calculator also uses the Texas Instruments AOS algebraic operating system and the APD automatic switch-off feature.

The calculator has a large 8-digit liquid-crystal display, and incorporates full scientific notation (5-digit mantissa and 2-digit exponent display format) and mantissa expansion capability. The algebraic operating system includes 15 levels of parentheses and up to four pending operations, allowing the user to enter problems from left to right as they are usually written. The APD (automatic power down) feature automatically shuts the calculator off after about 15 min of non-use. The low-power-consumption liquid-crystal display and the internal circuitry help to provide up to two years' of normal operation on a single set of batteries. A 'battery-low' indicator is also provided.

Circle No. 60 on Reader Enquiry Card.

BioScience nylon bossheads

Nylon bossheads. BioScience. New glass-filled nylon bossheads in three sizes have been introduced by BioScience. Closed or open-sided versions are available, the former allowing bars to be held at right-angles or parallel to each other. Made of Maranyl, ICI's nylon compound, an extremely strong but light-weight material, they are virtually indestructible in normal use. The clamping screws are made of stainless steel. They have a good resistance to atmospheric corrosion and to most laboratory chemicals; are non-magnetic and of low thermal conductivity. They are, of course, washable. The larger of the closed type will accept bars up to 12.7 mm diameter. The smaller will take sizes up to 9.5 mm diameter. The open-sided version will hold bars from 3.2 to 12.7 mm diameter.

Circle No. 59 on Reader Enquiry Card.

Disposable ultrafilter. Millipore. The Immersible-CX molecular separator, a new disposable ultra-filter, provides a simple, rapid, and inexpensive means for concentrating and desalting proteins and other macromolecules in small to intermediate volumes of liquid. Each disposable unit contains 13 cm² of Pellicon ultrafiltration membrane and can process from 1 to 100 ml. The membrane, on a porous core through which vacuum is applied to drive filtration, is specially formulated for high flux and minimum nonspecific binding.

Circle No. 58 on Reader Enquiry Card.

In-line membrane filter holder. Sartorius. Recently announced by Sartorius is a 47 mm in-line filter holder (or with fittings—tap sampler) which is constructed in 316 stainless steel, with filter support, underdrain and back pressure screen coated in Teflon. A valve on the inlet side allows air venting or water removal (for example with PTFE filters) and the back pressure is removed or replaced by a twist.

Circle No. 57 on Reader Enquiry Card.

Multisheet chromatography tank. Gallenkamp. A new multisheet chromatography tank has been added to the Gallenkamp range. The tank can be used for one or two way ascending or descending chromatography and is designed to cater for a large number of samples at one time. Provision has been made for up to 10 250 × 250 mm papers on the aluminium frame for simultaneous ascending developments. Alternatively, two troughs are provided to hold paper for descending chromatography. A further pair of troughs can be used if required, and are available as accessories.

Circle No. 56 on Reader Enquiry Card.

Measuring syringes. Hamilton. Six new syringes with removable needles have been introduced into Hamilton's 700 series in sizes ranging from 5 to 500 μ l. All the 700s are now available with the added convenience and versatility of replaceable needles. Absolute liquid delivery is accurate to within $\pm 1\%$. Repeatable accuracy is within $\pm 1\%$. Bent or plugged needles can be easily replaced in the field. And the cost of added syringes is saved by simply replacing the needle. The needle threads securely in place so it cannot be pulled off by mistake. Carry over when changing samples is eliminated because there is virtually no dead volume. The syringe can be sterilised by all normal methods, including autoclaving. Each stainless steel plunger is individually tested and mated to its barrel to assure leak-proof sealing. They are shipped with one standard needle installed.

Circle No. 55 on Reader Enquiry Card.

Substrate for peroxidase staining. Northeast Biomedical Laboratories announce the introduction of a kit designed for use with both peroxidase-labelled antibodies and the PAP (peroxidase anti-peroxidase) complex. It is based on a non-carcinogenic substrate, aminoethyl carbazole. The kit includes the necessary buffer solutions, reagents for blocking endogenous peroxidase and nonspecific staining as well as pre-measured quantities of chromogen and carrier.

Circle No. 54 on Reader Enquiry Card.

Reverse-osmosis system. Millipore has extended its range of wall-mounted reverse osmosis systems. While retaining the advantages of high performance (90–99% rejection) and low operating cost, the new Milli-RO systems incorporate further significant advantages. Precisely designed and engineered to produce water at a rate of 125 and 250 l h⁻¹, the systems are based on a modular construction in 316 stainless steel and are easily dismantled for cleaning or cartridge replacement. The systems automatically flush to drain hourly for self cleaning and will shut off the pump when the feed water pressure is too low. Solid state controls also indicate low pressure cut-off, full tanks, system under flushing cycle and water saving.

Circle No. 53 on Reader Enquiry Card.

HPLC column. Applied Science. Applied Science Laboratories is now offering a new type of highly efficient, stable HPLC columns. These columns typically demonstrate 30,000 to 40,000 theoretical plates per m at a linear velocity of 0.14 cm per s, yet sustain pressures up to 6,000 p.s.i. or more. The columns are constructed of LiChroma stainless steel and are capped with zero or low dead volume unions containing removable frits. Packings are available with a complete range of surface functional groups. Columns can be supplied in 25 cm lengths and various internal diameters.

Circle No. 52 on Reader Enquiry Card.

Vacuum tight glass joints. Laboratory Impex. Unilok G retaining seals are a new laboratory aid bringing improved safety and efficiency to all apparatus assembled with standardised glass joints. The seals are extremely compact yet secure, ensuring gas-tight seals for both positive and negative pressures, without the need for extensive modifications to glassware.

Circle No. 51 on Reader Enquiry Card.

GC/MS Systems. Finnigan. The OWA-series GC/MS systems from Finnigan Instruments feature pre-programmed parameters built into the data system specifically to handle all organics-in-water problems. Despite low cost, the

OWA-series instruments exceed requirements for specificity, sensitivity, data integrity and an EPA-compatible data format/medium. Other features of the new system include low-cost data storage and transmission, and low-cost operation and maintenance.

Circle No. 50 on Reader Enquiry Card.

Gas chromatograph. Packard. The Packard model 430 dual channel integrating gas chromatograph uses a micro processor to control all analytical functions. This multi-user system can accept up to 15 users' analytical programs in store at any one time. An exclusive feature of the new system is its dual channel simultaneous integrator giving retention time, area counts and area per cent, and analytical program listing.

Circle No. 49 on Reader Enquiry Card.

HPLC injection valves. Schoeffel. The Schoeffel Instrument Division of Kratos, offers high pressure injection valves for liquid chromatography. These feature a rotary valve for injection, column switching and recycling, and include a high pressure, septumless syringe loading sample injector, with sample loops available from 10–100 μ l. A full line of accessories such as pneumatic actuators, mounting plates and fittings is also available.

Circle No. 48 on Reader Enquiry Card.

STOP FREEZING STOP SQUEEZING STOP LOSING TIME AND DNA

BRL'S LOW MELTING POINT AGAROSE

For rapid *in situ* redigestion of restriction enzyme cleavage fragments. Freeze – Squeeze¹ or Gel Dissolution – Chromatography² techniques are time-consuming, inefficient methods for recovery of DNA fragments from agarose.

When mapping restriction enzyme cleavage sites of DNA, BRL's Low Melting Point Agarose makes redigestion of large numbers of DNA fragments easy, rapid and economical.

BRL's Low Melting Point Agarose melts at 62°C, gels at 28°C and remains fluid at 30–37°C for several hours. Parker and Seed³ have recently developed a simple, efficient method for *in situ* redigestion of DNA fragments after electrophoresis through low melting point agarose. A detailed protocol for this enzyme-saving, time-saving technique is included with the Product Profile Sheet shipped with each order of BRL's Low Melting Point Agarose.

Steady-State Enzyme Kinetics

Stanley
Ainsworth

Identifies the basic ideas of the subject for the graduate and advanced undergraduate student, and familiarises the reader with them so that they may then be applied to any problem likely to be encountered. Although it cannot altogether avoid mathematical presentation, almost all the equations used require only an elementary acquaintance with algebraic manipulation. Moreover the arguments themselves are presented as fully as possible to enable the reader to progress easily from each stage to the next.

Balzers 07 120 sputtering device

Sputtering device. Balzers. An improved version of the Sputtering Device 07 120 for the preparation of electron microscopy specimens is available from Balzers High Vacuum Limited. The device has a rotary symmetrical magnetic field and, because the target and specimen table are water-cooled, a high sputter rate can be maintained without the specimen temperature rising beyond approximately 25 °C. The specimen surface is easily cleaned, an etching device being brought into operation simply by changing plugs on the unit. A built-in aperture enables samples to be etched and then sputtered without interrupting the vacuum as well as the pre-sputtering of difficult films such as oxides of nickel and chromium.

Circle No. 47 on Reader Enquiry Card.

Aggregation meter. Sienco. An improved version of the Sienco dual sample platelet aggregation meter, featuring reduced sample requirements and improved optics, has been announced. With a minimum sample requirement of only 0.2 ml, as well as standard 0.4 ml, the Sienco Model DP-247-E is especially useful instrument for pediatric and other applications where only small samples are available. The meter depends on optical transmission through a cuvette, generates two simultaneous curves on a single pen or two pen recorder in identical sample conditions. The dual run capability allows the choice of several sample combinations, saves time, and minimises plasma deterioration. A key application for the Sienco aggregation meter is the detection and characterisation of haemostatic disorders associated with haemorrhagic problems (decreased aggregation) and thrombotic tendencies (increased aggregation). The instrument provides excellent aggregation resolution with lipemic plasmas as well as very low platelet count plasmas. In addition to platelet function determinations, the Sienco aggregation meter may also be used to measure plasma coagulation: it is well-suited for either routine clinical use or research into platelet function and blood coagulation.

Circle No. 46 on Reader Enquiry Card.

STEM Philips EM 400 microscope.

Philips. Advanced features for fast, efficient operation—plus unique signal mixing and display facilities—are included in a new STEM unit for the Philips EM 400 transmission electron microscope. Addition of the fully integrated STEM system to the EM 400 gives the microscopist a choice of three basic imaging modes and various analysis modes. Rapid switching between TEM, STEM and SEM is made possible by the provision of preset alignment controls, while up to six signals are push-button selectable. Any combination of the available signals can be superimposed on the viewing screen, permitting ready comparison of various types of information from a given specimen area. Alternatively, images can be displayed side by side in a split-screen presentation. A dual magnification system gives the further option that a signal can be viewed at a selected magnification on one half of the screen, while simultaneously being shown alongside at a zoomed value 1× to 4× larger. Using the split-screen mode, two successive exposures can be made on the same piece of film at different goniometer tilt angles, providing a correctly aligned stereo pair. Independent adjustment of brightness and contrast allows easy choice of different imaging modes. Line time and number of lines are also independently controlled, giving a wide choice of frame speeds and enabling the best scanning conditions to be selected for each application. A special 1000× line time facility produces excellent counting statistics for X-ray analysis. The STEM unit is complemented by a wide range of modular plug-in accessories for the optimisation, manipulation and recording of scanned images.

Circle No. 45 on Reader Enquiry Card.

Water-jacketed CO₂ incubator.

Forma. The CH/P System adds a new dimension to solid-state electronic CO₂ control with direct digital CO₂ setpoint to within 0.1% over a full 0–20% range and direct digital display of both setpoint and chamber readout on one easy-to-read LED indicator. The direct digital CO₂ setpoint and digital CO₂ display electronically locks-in for precise CO₂ control. A CO₂ deviation alarm provides an audible and visual warning if CO₂ tension drifts more than 1% from setpoint. Sensor fans gently circulate chamber air to eliminate CO₂ stratification, to improve temperature uniformity and to hasten temperature recovery after door openings. The Model 3325 has a temperature range of 2 °C above ambient to +60 °C, a solid-state direct reference dial, and 37 °C fixed-point selector switch. This unit with two independent chambers, two CH/P System Controllers occupies only 4 square feet of floor space. CH/P System digital CO₂ controllers are now available on all Forma automatic water-jacketed incubators.

Circle No. 44 on Reader Enquiry Card.

Low-cost spectrophotometers. Pye Unicam. The SP6 Series of low cost, single beam UV/visible spectrophotometers now feature major improvements in performance, versatility and construction. Four instruments are available offering the choice of visible or UV/visible range and digital or meter display. New accessories include an automatic cell changer, a thermoelectric heated and cooled holder and a low cost programmable calculator offering autozero and autoconcentration modes or enzyme range and immunoassay computations.

APPOINTMENTS VACANT

HUMAN SCIENCES

We have an opportunity for a graduate to contribute to the ergonomics programme of the Institute of Occupational Medicine, which is the coal industry's research centre for medical and allied problems. The programme involves a wide range of ergonomics investigations in coal mining, chemical and other industries. The successful candidate will be appointed to the Human Sciences Group and will initially work in the field of occupational stress.

The Ergonomics Branch is a large multi-disciplinary team with good supporting facilities and is situated at Boreby, nine miles south of Derby.

Salary, dependent on age and experience, will be in the range £4,000 to £5,000. Excellent conditions of employment include generous leave.

Please apply to:

Head of Staff Recruitment/Training,
National Coal Board,
Scottish Area,
Green Park,
Greenend,
Edinburgh EH17 7PZ. 252(A)

THE MEDICAL COLLEGE OF ST BARTHOLOMEW'S HOSPITAL (University of London) West Smithfield, London EC1A 7BE

Applications are invited from good honours graduates or those expecting to graduate in 1979 in Biochemistry or related subjects, for the post of

RESEARCH ASSISTANT

to undertake investigations on the biochemistry of chemical carcinogenesis. The successful candidate will be registered for the degree of PhD.

The appointment, funded by the M.R.C., will be for three years and will be at an initial salary of £3,384 p.a. plus £502 London Allowance.

Enquiries to Professor E. M. Crook, Biochemistry Department, The Medical College of St Bartholomew's Hospital, Charterhouse Square, London EC1M 6BQ.

Applications in writing to The Secretary of the Medical College at the West Smithfield address, quoting reference 829. 220(A)

THE UNIVERSITY OF LEEDS DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a temporary post of

RESEARCH ASSISTANT

to work on the molecular biology of the acquisition of bacterial drug resistance in association with Dr J. H. Parrah in the above Department. The post would be most suitable for a postgraduate with appropriate research experience, although persons graduating this year in Biochemistry, Genetics, Microbiology, or an appropriate combination of these subjects, will be considered. The appointment will be made with effect from October 1, 1979, for a fixed term of two years.

Salary at an appropriate point on the IB Scale for Research and Analogous Staff (£3,384 to £4,882) (under review), according to age, qualifications and experience.

Application forms and further particulars may be obtained from The Registrar, The University of Leeds, Leeds LS2 9JT, quoting reference number 83/19/D. Closing date for applications April 30, 1979. 259(A)

UNIVERSITY OF DURHAM DEPARTMENT OF BOTANY

Applications are invited from candidates with interests in molecular and microbial genetics for the post of

LECTURER IN GENETICS

tenable from October 1, 1979. Experience in recombinant DNA technology preferred.

Salary of the scale £3,883 to £7,716 (under review) plus superannuation.

Applications (3 copies) naming the referees should be sent by May 1, 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 1LE (from whom further particulars may be obtained). 218(A)

PLANT BREEDING INSTITUTE

Maris Lane, Trumpington,
Cambridge CB2 2LQ

A vacancy exists for a Scientific Officer/Higher Scientific Officer for project funded by the Home Gro Cereals Authority for the period December 31, 1980. The officer appointed is required to take responsibility for the development of application of methods for the rapid identification of malting quality barley. The work will be of chemical/biochemical nature aimed at determining differences in the structure and metabolism of barley genotypes.

Minimum qualifications required an Honours Degree or equivalent Chemistry or Biochemistry or ordinary degree, H.N.C., with experience.

The appointment will be as Scientific Officer (£2,839 to £4,414 per annum or Higher Scientific Officer (£4,101 to £5,448 per annum). At least five years relevant postgraduate experience required for appointment as Higher Scientific Officer.

Applications with curriculum vitae and names and addresses of three referees should be sent to the Assistant Secretary (Establishment), quoting CER 49, by April 20, 1979. 222(A)

UNIVERSITY OF CAMBRIDGE
DEMONSTRATOR IN PLANT PHYSIOLOGY. Applications are invited for a University Demonstratorship in the Department of Botany to commence on October 1, 1979. The person appointed will be expected to assist in teaching some of the following: integrated cell biology course, cell or whole plant physiology, plant development. The applicant should have research interests in some aspect of plant physiology. The appointment will be in the first instance for 3 years with a maximum tenure of 5 years. The salary is on an incremental scale rising from £4,133 to £5,129 per annum. Applicants, with the names of three referees, should be sent by May 1979 to the Secretary of the Faculty of Biology 'A' Appointments Committee, Department of Applied Biology, Pembroke Street, Cambridge CB2 3PQ from whom further particulars may be obtained.

Registration Officer

We are a major International Company manufacturing ethical pharmaceuticals. The Company has been successful in recent years in identifying a series of valuable new medicines and has a continuing research programme involving further potential new medicines.

The Registration group is a small team of graduates whose principal function is the organisation of scientific data for presentation to the Committee on Safety of Medicines.

A post of Registration Officer in this department is now vacant. Candidates should be graduates in a biological science, should have facility in the organisation of scientific data and the ability to write clearly and concisely on scientific topics. Previous experience of product registration or other experience within the Pharmaceutical Industry would be an advantage.

Please apply to:-

Personnel Officer,
Wyeth Laboratories
Huntercombe Lane South, Taplow,
Maldenhead, Berks. Tel. Slough 28311.

Wyeth Laboratories

THE OPEN UNIVERSITY FACULTY OF SCIENCE

Biology Electron Microscope Technician

We require an experienced technician to maintain and operate a recently purchased Joel JEM 100S Electron Microscope and its ancillary equipment housed in a new purpose built EM suite. This sectioning equipment includes Reichert OMU3 and Cambridge Huxley ultrathin sections. Access to scanning electron microscope facilities are also available. The post offers an opportunity to a technician seeking employment in an expanding area of a unit which serves both the teaching and research requirements of the Discipline. Applicants should have a HNC or equivalent and 10-12 years' practical experience preferably in Biological Electron Microscopy. Commencing salary will be within the Technician Grade 6 scale £3,884 to £4,365 per annum (under review). Application forms and further particulars are available from The Recruitment Office (JD438/1), The Open University, P.O. Box 75, Walton Hall, Milton Keynes MK7 6AL, or telephone Milton Keynes 63888. 24-hour answering service. Closing date for applications 23rd April, 1979. 272(A)

PROFESSORSHIPS

in PHYSICS, ELECTRICAL ENGINEERING MATHEMATICS & BALLISTICS

The Royal Military College of Science runs first degree, post-graduate, army staff and special courses on a wide variety of subjects. While the College's primary function is the scientific education of the Army officer at all stages of his career, courses are also attended by civilians, and military personnel from overseas.

The College is a residential establishment occupying a large estate in the Vale of the White Horse, near Swindon, and has an academic staff of over a hundred. Research is an important part of the work, and there is every opportunity for staff to pursue their own research interests and publish findings.

The excellent facilities and equipment include a nuclear laboratory, workshops and ICL 1903A, PDP 11/45 and PDP 11/20 computers with a wide range of peripherals.

Due to retirements, the following posts will shortly fall vacant. The new appointments may be permanent and pensionable, or (with present employee's agreement) on secondment terms. Candidates must have a record of high professional attainment, and have had considerable relevant experience, including some teaching at university level.

Chair in Physics

The Department is responsible for the teaching of physics as required for all courses at the College. In addition, special instruction is given on nuclear radiation and weapons effects. Research interests centre on solid state and nuclear physics, mainly polymer studies (including pulsed NMR), radiation effects on polymers, radiation grafting, nuclear techniques for materials study, solar cells, new tools for atmospheric studies, and applications of photon autocorrelation.

Salary will start between £11,710 and £12,730, according to qualifications and experience. Ref: S/9828/3.

Chair in Electrical and Electronic Engineering

The professor will be responsible for the full range of work of this large Department. In addition to teaching to degree and other academic courses, instruction is given on guided weapons, digital systems, computer hardware and signal processing. Current fields of research interest include antenna design, microwave integrated circuits, a load simulator for large control systems, and digital feedback communication systems.

Applicants for this position must hold, or be eligible for, corporate membership of the IEE.

Salary will start between £11,710 and £12,730, according to qualifications and experience. Ref: S/5109/3.

Associate Professor— Mathematics and Ballistics

The Associate Professor will be responsible for the teaching and research activities of the Mathematics and Ballistics Branch. Its present research programme covers control system theory; boundary value problems in mathematical physics; approximation theory and numerical analysis; quality assurance and reliability; mathematics of wave power machines; internal ballistics; blast waves; transient vibration analysis of gun barrels; and the stability of projectiles, including liquid filled projectiles.

Salary will start between £10,040 and £11,300, according to qualifications and experience. Ref: S/5107/3.

For further details and an application form (to be returned by April 24, 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (an answering service operates outside office hours).

Please quote the appropriate reference.

THE UNIVERSITY OF LEEDS

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a temporary post of

TEACHING FELLOW

in the above Department. Candidates should either have a Ph.D. in Biochemistry or a closely-related discipline or be about to submit for a Ph.D. Degree. The person appointed will participate in teaching biochemistry to science and medical students and will also be expected to engage in research, preferably in an area already under investigation in the Department. The appointment will be made with effect from October 1, 1979, for a fixed term of three years.

Salary at an appropriate point on the 1A Scale for Other Related Staff (£3,883 to £6,555) (under review), according to age, qualifications and experience.

Application forms and further particulars may be obtained from The Registrar, The University of Leeds, Leeds LS2 9JT, quoting reference number 83/20/D. Closing date for applications: April 30, 1979. 257(A)

EDINBURGH UNIVERSITY

PHYSICS DEPARTMENT

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for this post to work on the Raman scattering of molecular systems under high pressures. Financial support is available from S.R.C. for the initial phase of this work until April 1980, with good prospects for continued support. Use will be made of the department's excellent Raman scattering laboratory which enjoys interactive computer control. A high pressure cell, capable of over 500 kbar, is nearing completion and exploratory experiments will soon be started. Experience in either Raman or high pressure techniques is desirable, but not essential. The work will be done under the supervision of Dr G. S. Pawley.

Applications, with a curriculum vitae and the names of two referees, should be sent to Professor R. A. Cowley F.R.S., at the Physics Department, Kings Buildings, Edinburgh EH9 3JZ.

221(A)

AGRICULTURAL RESEARCH COUNCIL

Institute for Research on Animal Diseases

A vacancy exists in the Department of Immunology and Parasitology for a

RESEARCH SCIENTIST

to work on cellular immunity related to helminth infections (including liver fluke) of domestic livestock. The person appointed will join a team investigating the development of immunity to parasitic diseases. Studies will include the immunological function of different cell types and the isolation of antigens which will stimulate immunity for the protection of farm animals.

Qualifications: A first or upper second class honours degree, or equivalent with 4 years relevant postgraduate experience in immunology. Applicants must have an interest in parasitology.

Salary Scale: Appointment will be to the Senior Scientific Officer scale £5,154 by 8 to £6,898 per annum. The A.R.C. pension scheme is non-contributory.

Application forms:

Secretary,

Institute for Research on Animal Diseases,
Compton, Newbury, Berkshire.

Quoting Ref: 271.

269(A)

UNIVERSITY OF JOS, JOS, NIGERIA VACANCIES

In the Faculty of Medical Sciences

Applications are invited from suitably qualified candidates for appointments in the Department of Anatomy, Faculty of Medical Sciences of the University of Jos.

A. READER

Qualifications: Candidates should possess a good Medical Degree with postgraduate qualifications in either M.S., M.E., Ph.D. or D.Sc. (Anatomy). Teaching experience in Human Anatomy, Histology and Embryology in any recognised Medical Colleges/Universities at undergraduate and postgraduate levels for at least seven years is essential. Experience in administration and supervision of postgraduate research is desirable.

B. SENIOR LECTURER

Qualifications: Candidates should possess either M.S., M.Sc., or Ph.D. (Anatomy/Histology). Postgraduate teaching experience in Anatomy, Histology and Embryology in Medical Colleges/Universities for M.B., B.Sc. Classes for at least three years is essential.

C. LECTURER I

Qualifications: Candidates should possess postgraduate qualifications in either M.S. or M.Sc. (Anatomy). Postgraduate teaching experience in Anatomy, Histology or Embryology is desirable. Candidates with postgraduate qualifications in general surgery, that is M.Sc. Surgery or F.R.C.S. could be considered if they hold established teaching post in Anatomy in recognised Medical Colleges/Universities.

D. SALARY

Reader GL. 14—N8,868 by 320, N9,828 per annum.
Senior Lecturer GL. 13—N7,764 by 320, N8,724 per annum.
Lecturer I GL. 11—N6,444 by 180, N6,984 per annum.

E. CONDITIONS OF SERVICE

Successful candidates will be on probation for the first two years and afterwards confirmed to retiring age if their services are considered satisfactory. Other fringe benefits include pension scheme, car allowance, part furnished accommodation or housing allowance in lieu of accommodation. Twenty-five per cent contract addition is payable to all expatriates.

F. METHOD OF APPLICATION

Candidates should send their Curriculum Vitae in six (6) copies giving the following details; Name, Age, Nationality, Marital Status, Educational Institutions attended with dates, Work experience (i.e. post held, duration and salary earned), names of three referees at least two of whom should be competent to attest to the candidates professional/academic standing and characters. Candidates should request their referees to send their confidential reports under confidential cover to the address below. All applications should be sent to:

REGISTRAR,
UNIVERSITY OF JOS,
P. M. B. 2084,
JOS, NIGERIA

Applicants resident in the UK should also send a copy of their C.V. to the Principal Assistant Secretary (Recruitment) at the Nigerian Universities Office, 180 Tottenham Court Road, London W1P 9LE. 251(A)

UNIVERSITY OF WALES university college of swansea

SENIOR RESEARCH ASSISTANT

High Performance Semiconductor Oxides

A Senior Research Assistant is required for an S.R.C. grant investigating chemical changes in semiconducting oxides exposed to reducing environments, with the aim of developing gas detectors which will exhibit specificity to certain gases. Instruments which incorporate these detectors will be designed within the Electrical Engineering Department.

Applicants should have a good honours degree and preferably research experience in solid state chemistry or an immediately relevant subject.

The appointment is for three years, commencing as soon as possible and the remuneration will be up to £4,382 per annum plus USS/USDPs benefits.

Prospective candidates may contact Dr K. J. Gallagher of the Chemistry Department but further particulars and application forms (two copies) should be obtained from the Personnel Officer, to whom they should be returned as soon as possible.

RESEARCH DEMONSTRATORS

Applications are invited for two vacancies of Research Demonstrator in the Department of Genetics involving laboratory and tutorial teaching in Genetics. Candidates should have, or expect in the near future to have, a Ph.D. and be active in research. For one post (a) experience in evolutionary or human genetics, and for the other (b) experience in microbial genetics is desirable.

Appointment (a) is available from April 1, 1979, or as soon as possible thereafter, (b) from October 1, 1979. Both appointments will be on a scale up to £4,382 (under review) together with USS/USDPs benefits. Closing date for applications, Friday, April 13, 1979.

Further particulars for the above posts and application forms (2 copies) may be obtained from the Personnel Officer, University College of Swansea, Singleton Park, Swansea SA2 8PP, to whom they should be returned by the above dates. 256(A)

UNIVERSITY OF BRISTOL DEPARTMENT OF PHYSICS TECHNICIAN GRADE 5 £3,186 to £3,720 per annum (scale under review)

Applications are invited for the above post which falls vacant April 1979. The requirement is for a technician to assist in the teaching laboratory of a graduate course in Physics of Materials in which a range of mechanical testing equipment, optical microscopes, metallographic and vacuum apparatus, furnace and X-ray facilities are housed. The successful applicant, under supervision of a member of the academic staff, is responsible for maintaining this equipment and assisting in its demonstration to graduate students.

Preferred qualifications would be at HNC level or equivalent. Applications, stating age, experience and qualifications should be made to: Dr D. Dingley, H. H. Wills Physics Laboratory, Royal Fort, Tyndall Avenue, Bristol BS8 1TL, from whom further particulars can be

THE UNIVERSITY OF LEEDS DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a temporary post of

TEACHING ASSISTANT

In the above Department from candidates with suitable postgraduate or postdoctoral experience. The person appointed will participate in teaching biochemistry to science and medical students and will also be expected to engage in research in an area already under investigation in the Department. The appointment will be made with effect from October 1, 1979, for a fixed term of two years.

Salary at an appropriate point on the grade 1B Scale for Other Related Staff (£3,384 to £5,604) (under review), according to age, qualifications and experience. Application forms and further particulars may be obtained from The Registrar, The University of Leeds, Leeds LS2 9JT, quoting reference number 83/21/D. Closing date for applications, April 30, 1979. 258(A)

UNIVERSITY OF NAIROBI KENYA

Applications are invited for posts of SENIOR LECTURER IN DEPARTMENT OF METEOROLOGY. Applicants should have a Ph.D. in Meteorology with a minimum of three years research and teaching experience at a University level in at least one of the following branches: Dynamic Meteorology, Synoptic Meteorology, Climatology, Pollution Meteorology, Agrometeorology, Hydrometeorology, Physical Meteorology and Cloud Physics. The appointees teach under graduate and postgraduate courses and also organise and supervise research at postgraduate level. Salary scale K22,988 to K23,984 per annum (K2 equals £131 Sterling). The British Government may supplement salaries by £5,430 per annum (Sterling) for married appointees or £3,648 per annum (Sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowance and holiday visit passages SSSF or FSSU, family passages, medical and scheme, housing allowance, various allowances. Details applications (two copies) including curriculum vitae and naming three referees should be sent by air mail not later than May 3, 1979 to the Registrar, (Recruitment and Training) University of Nairobi, P.O. Box 3019, Nairobi, Kenya. Applicants resident in U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. 270(A)

UNIVERSITY OF THE WITWATERSRAND JOHANNESBURG CHAIR OF MICROBIOLOGY

Applications are invited for the Chair of Microbiology, within the School of Biology, in the Faculty of Science. The interests at present of this division of Microbiology are: (a) Industrial Microbiology, (b) Microbial Ecology, (c) Microbial Genetics, (d) Immunology and Virology. Applicant with experience in the above, or other microbiological specialist areas will be considered.

The salary allocated to the post is in the range R12,949 to R16,546 per annum, the initial salary to be determined according to qualifications and experience. A salary review is expected in April 1979.

The University's policy is not to discriminate in the appointment of staff or the selection of students on the grounds of sex, race, religion or colour. Further particulars relating to this practice and to the above post are included in an information sheet obtainable from the London Representative, University of the Witwatersrand, Chichester House, 77A High Holborn, London WC1V 7HE or from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa, to whom applications should be lodged.

BIRZEIT UNIVERSITY

An independent Arab University in the Israeli-occupied West Bank of Jordan has the following faculty openings for the academic year 1979/1980: Biology — Biochemistry, Chemistry (Physical, inorganic, organic), Mathematics (Algebra, Analysis, Mathematical Statistics), Physics (Experimental and Theoretical). English is the basic language of instruction and candidates should have a Ph.D. preferably or a master's degree with experience. Starting annual salary for Ph.D. is 2,700 Jordanian Dinars (current exchange rate, 1 J.D. = about £17). Optional summer teaching extra. Fringe benefits include: Relocation allowance (15% of salary), Transportation also provided. All applications should be addressed to Dean of the Faculty of Science, Birzeit University, Birzeit, West Bank Via-Israel.

26(A)

POSITION AVAILABLE

DIRECTOR, Institute of Animal Resources Ecology, University of British Columbia, position vacant as of July 1, 1979. The Institute is a postgraduate centre for teaching and research with emphasis on innovative approaches and multi-disciplinary constructs in ecological science and resource management. Because the Institute has strong roots in biology, the applicant must have understanding of biological sciences but need not necessarily be a zoologist or ecologist. He should be prepared to serve the Institute's main goal of innovative research that bridges gaps between traditional disciplines, methods and institutions. Applicants and curriculum vitae, including at least three references, should be sent to Dr A. R. Thompson, Director, Westwater Research Centre, University of British Columbia, 1933 West Mall Annex, Vancouver, B.C., Canada, V6T 1W5, to arrive not later than May 15, 1979.

W22(A)

**IMMUNOLOGY
POSTDOCTORAL
RESEARCH ASSOCIATE
DARTMOUTH
MEDICAL SCHOOL**

Hanover, New Hampshire, USA

Immunologists are invited to apply for a postdoctoral position to work with a group on a project concerned with the proliferation, maturation, and differentiation of T-lymphocytes. The emphasis is on the interaction of soluble regulatory factors with their target cells. Experience in cellular immunology, protein biochemistry, and/or radioimmunoassay is desirable. The position is for two to three years and is available after July 1, 1979. The salary is according to qualification and experience (\$12,000 to \$18,000/yr.). Applications including curriculum vitae, a description of research experience, relevant reprints and the names and addresses of two referees should be sent to Dr Kendall A. Smith, Dartmouth Medical School, Hanover, NH 03755, USA.

W21(A)

**BEDFORD COLLEGE
(University of London)
LECTURESHIP IN
GEOLOGY**

Applications are invited for a Lectureship in Geology from October 1, 1979 from persons with experience and research interests in the field of petrology involving mineralogy and geochemistry. It is expected that the successful applicant will be conversant with geochemical analytical techniques, particularly in the X-ray field, and will undertake the supervision of the Department's geochemical laboratories. Gross salary scale £4,477 to £8,752 per annum (under review). Particulars and application forms, returnable by April 29, are available from Senior Assistant Secretary (Personnel), Bedford College, Regent's Park, London

DEPARTMENT OF PHYSICS

Applications are invited for the post of

LECTURER

in the Department of Physics. Candidates should have an active research interest in Quantum Physics and experience with the use of fields and groups. The person appointed will be expected to interact effectively with the Theoretical High Energy Physics group and to play a full part in the Department's programme of teaching in theoretical physics.

Salary scale £3,883 to £7,754 per annum plus U.S.S. The initial salary will depend on qualifications and experience. Further particulars may be obtained from Mrs E. C. P. Sears, Staffing Section, The University Southampton SO9 5NH to whom applications (7 copies from United Kingdom applicants) should be sent not later than May 18, 1979. Please quote reference number 1403/A.

253(A)

THE UNIVERSITY OF LEEDS

DEPARTMENT OF ORGANIC CHEMISTRY

Applications are invited for a temporary post of postdoctoral

RESEARCH FELLOW

in the above department to undertake work with Dr R. B. Herbert, on a project sponsored by the M.R.C. on the structure and biosynthesis of vitamin D derivatives in plants. Candidates should already possess or expect to obtain a Ph.D. degree in the near future. The appointment will be made for a fixed term of two and a half years from October 1, 1979, or from a date to be arranged.

Starting salary in the range £3,883 to £4,382 of the I.A. scale for Research and Analogous Staff (£3,883 to £6,555) (under review), according to age, qualifications and experience.

Applications (quoting reference number 45/9/D) should be made as soon as possible to the Registrar, The University, Leeds LS2 9JT (from whom further particulars may be obtained).

**UNIVERSITY OF
WESTERN AUSTRALIA
Perth**

**SENIOR RESEARCH
OFFICER IN CLINICAL
IMMUNOLOGY
DEPARTMENT OF
PATHOLOGY**

This N.H. and M.R.C. funded position is intended for a science graduate with experience in immunopathology, biochemistry, immunology or cell biology to join a research team working on autoimmune disease with particular reference to contractile protein and receptor antigens, immunoregulation and histocompatibility. The Department also provides a comprehensive clinical immunology service. Salary range \$A15,786 to \$A20,737 per annum.

Applications in duplicate stating full personal particulars, qualifications and experience to reach the Staffing Officer, University of Western Australia, Nedlands, Western Australia, 6009 by May 1, 1979. Candidates should request

CSIRO AUSTRALIA

Institute of Animal & Food Sciences

Chief of Division

**Division of Food Research
Sydney NSW**

Applications are invited for the position of Chief, Division of Food Research, from scientists who have an established record of personal research achievement and leadership in food science or related disciplines. The position has become vacant on the appointment of the former Chief, Mr. M. V. Tracey, to the position of Director of the Institute of Biological Resources, CSIRO.

CSIRO is Australia's largest and most comprehensive research organization, having approximately 7,000 employees of whom 2,400 are research and professional scientists. Its broad charter covers research into problems of primary and secondary industries and also such fields of community interest as human nutrition, the environment and the development and use of natural resources. The Organization has recently grouped its research activities in five Institutes and one Bureau, and the Division of Food Research is one of the Divisions within the Institute of Animal and Food Sciences.

The components of the Institute are the Divisions of Animal Health, Animal Production, Food Research, Human Nutrition, the Molecular and Cellular Biology Unit, the Wheat Research Unit and the Centre for Animal Research and Development in Indonesia.

The Division of Food Research has three main laboratories: the Food Research Laboratory in Sydney, NSW, the Meat Research Laboratory in Brisbane, Queensland, and the Dairy Research Laboratory in Melbourne, Victoria. There is also a Food Research Unit in Hobart, Tasmania. The headquarters of the Division are located in the Food Research Laboratory. The total staff of 338 includes 162 professional scientists.

The Division of Food Research conducts research programs in food science and technology directed generally towards improvements of the quality of fresh and processed foods both for Australian consumers and for export markets. Specific programs are concerned with the micro-biological status and safety of foods; the nutritional status, quality and structure of foods; the minor components of foods of sensory and physiological significance; and the development of improved procedures for the handling, storage, transport, and processing of foods in the commodity groups: meat, dairy products, seafoods, poultry, eggs, fruits and vegetables.

A Chief of Division is responsible for the leadership, development, scientific direction and integration of the research programs of the Division, and is encouraged to promote active collaboration with other Divisions, industry and research bodies working in associated areas. A recent review of the work of the Division of Food Research recommended the strengthening of relations with the Australian food industry.

The salary for the position is negotiable but will not be less than \$A34,374 per annum.

The terms of the appointment will be discussed with the short-listed applicants at interview. The appointee would be eligible to contribute to the Commonwealth Superannuation Scheme, subject to certain conditions.

Further information on the Division is in a booklet available on request from the Secretary, CSIRO, at the address below.

Dr. K. A. Ferguson, Director of the Institute of Animal and Food Sciences, and Chairman of the Appointment Committee, will be visiting North America in April/May 1979 and the United Kingdom in early June 1979 and will be available for discussions concerning the appointment with applicants and other interested parties. Those interested should contact either the Minister (Scientific), Australian Scientific Liaison Office, Canberra House, 10-16 Maitland Street, London WC2R 3EH, England, or the Counsellor (Scientific), Australian Embassy, 1601 Massachusetts Avenue NW, Washington DC 20036, USA. It may be possible to arrange such discussions at a number of points in the United Kingdom and the USA. Interested scientists should ensure that the appropriate overseas office is contacted in ample time to enable suitable arrangements to be made.

Applications stating full personal and professional details and names of at least two professional referees and quoting reference number 300/729 should reach:

The Secretary
CSIRO, PO Box 225
DICKSON ACT 2602
AUSTRALIA

by 27 April, 1979 (248A)

**Science Research Council
Daresbury Laboratory**

The Daresbury Laboratory has a vacancy in the theory group for a

SOLID STATE THEORETICIAN

The position is a permanent one at Higher Scientific Officer level.

The successful applicant will be expected to take a strong interest in numerical computations of relevance to experiments planned for the new facilities. Applicants should possess a Ph.D in solid state theory or expect to obtain one during 1979.

At the laboratory a purpose-built X-ray and ultraviolet source and a major nuclear structure facility based on a 30 MV tandem Van de Graaff are under construction. An IBM 370/165 computer is installed at the laboratory, and a computational science group has recently been established working mainly in the quantum chemistry area.

Appointments will be made at salaries between £4101 and £5448, the level at which the HSO is appointed depending on age, ability and experience.

Closing date: 1 May 1979

For further information please write to or telephone the head of the theory group, Dr. J.B. Pendry (Tel. No. (0925) 65000, Extension 223). Applications, from either sex, should be sent together with curriculum vitae and the addresses of two referees, quoting reference number DL/665/1 to:

The Personnel Officer

HEMODYNAMICS AND
BLOOD FLOW STUDIES**

University of Illinois

Eye and Ear Infirmary
and

Abraham Lincoln School
of Medicine

The University of Illinois
at the

Medical Center, Chicago

Equal Opportunity/Affirmative
Action Employer

Applications are invited for a faculty position at the assistant or associate professor level. The major responsibility will be supervision of research of vascular flow in the retina, utilising a unique non-invasive computerised ophthalmoscopy system. Active interchange with engineers and clinical ophthalmologists will be fostered. An advanced degree (Ph.D. or M.D.) is a prerequisite.

Those interested should direct inquiries together with a curriculum vitae and bibliography to:

Morton F. Goldberg, M.D.
Professor and Head
Department of Ophthalmology
University of Illinois Eye and
Ear Infirmary
1855 West Taylor Street
Chicago, Illinois 60612

**THE EAST OF SCOTLAND
COLLEGE OF AGRICULTURE**

ANIMAL BREEDING SPECIALIST—GRADE III/IV

ANIMAL PRODUCTION ADVISORY AND DEVELOPMENT DEPARTMENT

(Ref: N 237)

Applications are invited for the above post in the Animal Production Advisory and Development Department. Applicants should have postgraduate experience in Animal Breeding and an interest in the problems and methods of on-farm livestock improvement. The post will particularly concern breeding and development work with dairy cattle and sheep, although advisory expertise will be required for all farm livestock.

Salary, on the scale for Grade IV or Grade III according to experience and qualifications, as follows: Grade IV, £2,998 to £3,942; Grade III, £4,178 to £6,898. Non-contributory pension scheme.

For further particulars and application forms write to: The Secretary, The East of Scotland College of Agriculture, West Mains Road, Edinburgh EH9 3JG. Closing date for return of completed applications April 20, 1979. 233(A)

**THE AUSTRALIAN
NATIONAL UNIVERSITY**

Applications are invited from suitably qualified persons for appointment to the following position:

**THE JOHN CURTIN SCHOOL
OF MEDICAL RESEARCH**

**DEPARTMENT OF
MICROBIOLOGY**

RESEARCH FELLOW

The appointee will work with Dr G. Air and Dr W. G. Laver on the molecular biology of influenza virus variants. The project involves selection of influenza virus variants with monoclonal antibodies, then immunological analysis of their proteins and nucleic acids.

The appointment, which is funded by a grant from the National Institutes of Health, U.S.A., is for one year in the first instance with probable extensions for a further two years. It is hoped that the successful applicant would be able to take up the appointment in the near future.

Salary: Commencing salary will be in accordance with qualifications within the range \$A15,786 to \$A17,716. Current exchange rates are \$A1 : 56p : \$US1.13.

Other Conditions: A limited grant towards travel and removal expenses may be made. Assistance with housing is provided for an appointee from outside Canberra.

The closing date for receipt of applications is April 12, 1979. They should be sent to the Registrar, P.O. Box 4, Canberra, ACT 2600, Australia. 229(A)

Theoretical Physicists

The South African Atomic Energy Board has its headquarters at the National Nuclear Research Centre, Pelindaba, some 20 miles west of Pretoria.

The recently established Plasma Research Group hopes to put the first local tokamak machine into operation during 1979. Similar apparatus elsewhere has yielded promising results, and the Group is hopeful that, with a machine of this nature, controlled fusion will soon be demonstrated as a usable source of energy for the future. Research is planned on the instabilities of the tokamak plasma by employing a number of diagnostic techniques. Furthermore the Board has for several years conducted research in the field of nuclear physics and has a team of theorists actively engaged in the fields of nuclear theory and elementary particle theory.

The Board has vacancies for physicists who are qualified to Ph.D. level in the above fields of research.

General

Salary offered will be in accordance with qualifications and experience. Fringe benefits include: Medical Benefit Scheme, Assisted Housing Loan Scheme (after one year's service), Housing Subsidy Scheme, Pension and Group Insurance Scheme, Annual Leave Bonus, ample leave privileges and free transport between Pretoria and the Board's site.

A person appointed from overseas will receive financial assistance in regard to travelling expenses and the cost of

transporting his furniture and effects including a motor car. He is required to make use of all assistance given by the South African Department of Immigration and the amount received from the said Department will be deducted from the financial assistance offered by the Board. He is also required to serve the Board for two years in consideration of the financial assistance received. A non-South African appointee must undertake to apply for South African citizenship as soon as he qualifies. In certain cases the Board is prepared to consider appointments on contract for periods of 3 years.

Written applications, giving full details of qualifications, experience, and present salary, etc. should be addressed to: The Head, Personnel Administration, Atomic Energy Board, Private Bag X256, Pretoria 0001, Republic of South Africa.

ATOMIC ENERGY BOARD PELINDABA

187(A)

UNIVERSITY OF SHEFFIELD RESEARCH TECHNICIAN (Grade 5)

required for duties in the Space Physics Group within the Department of Physics for an initial period of three years from April 1, 1979. The successful applicant will be primarily concerned with the design, development, operation and maintenance of complex and sophisticated apparatus, equipment and instruments used in research into phenomena associated with the propagation of very low frequency radio waves.

Qualifications or experience should be of H.N.C. or equivalent standard. A current driving licence is essential and duties may include some travel both within the U.K. and abroad for periods of up to several weeks.

Salary on scale £3,186 to £3,720 per annum (under review).

Please write to the Administrative Officer (Personnel), (Ref. S1214/N), The University, Sheffield S10 2TN. 193(A)

UNIVERSITY OF BIRMINGHAM DENTAL SCHOOL Department of Oral Pathology RESEARCH FELLOW

Postdoctoral Research Fellow required to continue a project into the development of *in vivo* methods for testing the toxicity of dental materials. Previous experience of cell culture and quantitative cytochemical techniques would be an advantage, but is not essential. The project is for three years and would be carried out in parallel with other *in vivo* projects currently in progress.

Salary on the scale £3,883 to £6,555, plus superannuation; maximum starting salary £5,129.

Further particulars available from the Assistant Registrar, The Dental School, St Chad's Queensway, Birmingham B4 6NN, to whom applications, including a full curriculum vitae and the names of three referees should be sent by April 30, 1979. 247(A)

UNIVERSITY OF BIRMINGHAM ASSISTANT SAFETY ADVISERS

Applications are sought for two new posts of Assistant Safety Advisers from science graduates or professionally qualified persons, preferably with experience of health and safety work. The duties will be concerned with the use, handling, storage and disposal, in the one case of biologically hazardous materials and in the other of hazardous chemicals including carcinogens, poisons and dangerous drugs. If necessary additional training will be provided.

Salary in the scale £6,317 to £7,754 per annum (under review) with superannuation benefits.

Further particulars and application forms available from The Senior Assistant Secretary, University of Birmingham, P.O. Box 363, Birmingham B15 2TT, to whom application should be made by May 7 1979.

SCIENCE BOOKS EDITOR

This is a new post in the book review Department of The Times Higher Education Supplement. The job will entail commissioning and editing reviews of academic science books, page layout and production work. Applicants should have a good degree and copy-editing or sub-editing experience.

Please send full career details to:

BEDFORD COLLEGE (University of London) LECTURER IN BOTANY

Applications are invited for a Lectureship in Botany, from October 1, 1979. Applicants should have a research interest in the field of higher plant physiology and have a Ph.D. degree of a British University or its equivalent; some postdoctoral experience would be an advantage. Gross salary range £4,477 per annum to £8,752 per annum (under review). Particulars and application forms (returnable by April 19, 1979) available from Senior Assistant Secretary (Personnel), Bedford College, Regent's Park London NW1 4NS (Tel: 01-486

BEDFORD COLLEGE (University of London) LECTURER IN ORGANIC CHEMISTRY

Applications are invited for a Lectureship in Organic Chemistry from October 1, 1979. Applicants should have a Ph.D. degree of a British University or its equivalent; some postdoctoral experience would be an advantage. Gross salary range £4,425 per annum to £8,700 per annum. Particulars and application forms (returnable by April 23) available from Senior Assistant Secretary (Personnel), Bedford College, Regent's Park, London NW1 4NS (Tel: 01-486 4400).

BIRKBECK COLLEGE (University of London)

Applications are invited for the post of LECTURER IN EXPERIMENTAL PHYSICS with special reference to either Solid State Physics/Electronic or Nuclear and Particle Physics. Initial salary up to £4,655 per annum on scale £3,910 to £7,754 per annum (under review) plus London allowance of £450 per annum. Further details and application forms should be obtained from the Secretary, Birkbeck College, Malet Street, London WC1E 7HX. Closing date: April 19. 234(A)

PLANT BREEDERS AND AGRICULTURAL SEED SPECIALISTS

of
KING'S LYNN AND CHESTER
invite applications from
AGRICULTURAL TECHNICIANS

As part of the continued expansion of our Research and Development activities and Plant Breeding programmes we intend to appoint the following qualified male or female Agricultural Scientists with post-graduate experience in Plant Breeding or closely allied subjects as well as some agronomists.

Applications are invited from persons who will be able to work within a team structure, be prepared to travel widely and who can be available to start work during 1979.

Salaries and terms will be relevant to age, previous experience and will be negotiable.

BASED AT DOCKING, NEAR KING'S LYNN, NORFOLK
Plant Breeding Laboratory Manager

The successful applicant will be required to take over existing projects related to quality screening in wheat and barley and to service the other requirements of the breeding programmes. In our view a broad biological background is essential, and experience in one or more research and development functions supporting plant breeding would be advantageous.

This is a senior appointment involving liaison with research and development in Sweden, control of other scientific staff and establishing the functions and staffing of this section of the business in new premises currently being adapted. Therefore serious consideration will be given to scientific officers who can adapt themselves to commercial life and accept the responsibilities which this post presents.

Plant Breeder

The successful applicant will be required to take over the present kale and rape breeding programmes and arrange trials of maize and other forage crops as well as assisting in all aspects of winter cereal breeding programmes.

Pure Stock Multiplier

The successful applicant should have considerable experience in the production of pure stocks of cereal seed, either in the commercial field or at a research institute or other station.

A degree is not a pre-requisite of this applicant but Official Crop Inspector's and Seed Sampler's qualifications are desirable, and a good knowledge of the Seeds Regulations a distinct advantage. This appointment will be in the Variety Stock Control Department and presents good prospects.

BASED AT FARNDON, NEAR CHESTER, CHESHIRE
Plant Breeder

An additional plant breeder is required to assist in the Spring barley breeding work. The person appointed will be involved in every aspect of the programme, including international co-operation.

Forage Crop Agronomist

The execution of Agricultural and Amenity herbage variety trials at Farnndon and elsewhere will form a major part of this job. Other duties will involve participation in the management of the Breeding Station Farm and liaison with herbage breeders in other countries.

All the above appointments will qualify for the Company's contributory Pension and Life Assurance Scheme as well as free B.U.P.A. membership, and other fringe benefits.

Applications, which will be treated in confidence, should in the first instance be made with curriculum vitae, references and details of present position and salary, to Mr. D. G. Stiles, Company Secretary, The Miln Marsters Group Limited, Waterloo Street, King's Lynn, Norfolk, PE30 1PA. 243(A)

UNIVERSITY OF OXFORD

DEPARTMENT OF ZOOLOGY
ANIMAL ECOLOGY RESEARCH GROUP

**APPOINTMENT OF A DEPARTMENTAL
DEMONSTRATOR IN ANIMAL ECOLOGY**

Applications are invited for the post of Departmental Demonstrator in Animal Ecology from October 1, 1979. The successful candidate, who should recently have received a Ph.D. or be in his final year before submission, will be required to take part in ecology teaching and to undertake research in animal ecology.

The appointment will be for three years in the first instance with the possibility of renewal for a maximum of a further three years. The salary will be on University Scale £3,384 per annum (pre-doctoral) rising to a maximum of £4,466 per annum with membership of U.S.S.

Applications, including the names of two referees, should be submitted to Dr J. Philipson, Animal Ecology Research Group, Department of Zoology, South Parks Road, Oxford OX1 3PS, by April 30, 1979. 224(A)

**UNIVERSITY OF
STIRLING**

BIOLOGY DEPARTMENT

**LECTURESHIP/SENIOR
LECTURESHIP**

A vacancy exists in the Biology Department at Lecturer/Senior Lecturer grade to be filled by September 1, 1979. The successful applicant is expected to be involved in the teaching of plant ecology including field courses. An interest in numerical techniques and/or genetics would be an advantage.

Salary scales: Lecturer £3,883 to £7,754; Senior Lecturer £7,506 to £9,263 (both under review).

Applications, together with the names of two referees should be sent to the University Secretary (N), University of Stirling, Stirling FK9 4LA, from whom further particulars may be obtained. Closing date: April 20, 1979. 273(A)

(University of London)

Keppel Street, WC1E 7HT

**ROSS INSTITUTE OF
TROPICAL HYGIENE
LECTURER IN**

ENVIRONMENTAL HEALTH

The successful candidate will join an interdisciplinary group working on the evaluation and planning of health care in developing countries. He or she will be required to work on environmental health in primary health care, and should have appropriate overseas experience and relevant post-graduate training. The post will carry teaching and research responsibilities at this School and overseas.

The appointment, which will be initially for a period of up to three years, will be made to the university lecturer salary scale (£3,883 to £7,754 plus £450 London Allowance) currently under review. Application forms, which should be returned by May 18, 1979, and further information are available from F. C. Ball, Assistant Secretary. 246(A)

**UNIVERSITY COLLEGE
LONDON**

ICRF TUMOUR IMMUNOLOGY
UNIT

**TECHNICIAN/
RESEARCH OFFICER**

with an interest in electron-microscopy and ultrastructural research to work initially on a project concerned with histamine release from mast cells. Experience in thin section cutting preferred, but not essential. Degree/H.N.C. plus laboratory experience required.

Salary range £3,261 to £4,902 plus London Allowance.

For application form please telephone Mrs Nelson, Imperial Cancer Research Fund, Lincoln's Inn Fields, WC2 on 01-242 0200, extension 305. 225(A)

**UNIVERSITY COLLEGE
LONDON**

DEPARTMENT OF
CHEMISTRY

**POSTDOCTORAL
RESEARCH ASSISTANT**

required from approximately October 1, 1979 to work in collaboration with Dr T. M. Cresp on the total synthesis of biologically active sesquiterpenes. Salary in range £3,909 to £4,158 plus £450 London Allowance: U.S.S. The post is tenable for one year with possible renewal for a second year. Applications, consisting of curriculum vitae and names of two referees, should be sent to Dr T. M. Cresp, Department of Chemistry, University College London, 20 Gordon Street, London WC1H 0AJ, U.K. 183(A)

**UNIVERSITY OF
EAST ANGLIA**

Norwich

CLIMATIC RESEARCH UNIT

**A CLIMATOLOGIST/
METEOROLOGIST/
ENVIRONMENTAL
SCIENTIST**

with statistical experience is required as soon as possible to work until March 1981 on a project concerning the identification of changes in variability and the frequency of climatic extremes in the European Sector. Qualifications: Ph.D. with preferably at least two years postdoctoral experience. Salary will be within the range £4,382 to £6,080 on the Grade 1A scale for Research and Analogous staff plus F.S.S.U./U.S.S. benefits.

Applications (one copy) giving full particulars of age, qualifications and experience, together with the names of three referees, should be sent not later than April 7, 1979 to Administrative Assistant, Climatic Research Unit, University of East Anglia, Norwich NR4 7TJ, from whom further particulars may be obtained. 205(A)

**UNIVERSITY OF SURREY
DEPARTMENT OF METALLURGY
AND MATERIALS TECHNOLOGY**

Applications are invited
for the post of Redland

RESEARCH FELLOW

tenable in the Department of Metallurgy and Materials Technology at the University of Surrey.

The research programme carried out by the Fellow will relate closely to the research and development interests of Redland Limited, and the Fellow normally carries out a number of subsidiary investigations requested by the Company's Research and Development Centre. The post affords an excellent opportunity for the incumbent to familiarise himself with industrial research and to make the transition from academic to the industrial environment.

Applicants should have a Ph.D. or equivalent experience in some area of material science, or solid state chemistry. Preference may be given to candidates with interests or experience in silicate chemistry, Portland cement and ceramics. In view of the nature of the appointment, candidates having the ability to formulate new experimental approaches to unresolved problems would be preferred. The Fellow appointed will undertake research in materials of interest in construction and building and the main concern will be with property structure relationships of interest in developing new or improved materials.

The appointment would be made for two years in the first instance, renewable thereafter on a yearly basis.

Remuneration will depend on age and experience and will be in the range £3,883 to £5,129 (under review), on scales related to the University lecturers' scales. Applications, from men and women, in the form of a curriculum vitae, with the names and addresses of three referees, should be sent to: Professor J. E. Bailey, Department of Metallurgy and Materials Technology, University of Surrey, Guildford, Surrey GU2 5XH. 206(A)

**UNIVERSITY OF EXETER
DEPARTMENT OF PHYSICS**

Applications are invited for a post of
LECTURER

in Physics, tenable from October 1, 1979. The research field of interest is Medical Physics. Preference will be given to applicants with experience in hospital departments.

Salary on the Lecturers' scale £3,883 to £7,754 p.a. (under review).

Further particulars from Miss Doelen Watson, University of Exeter, Northcote House, Exeter, to whom applications (8 copies) should be sent by April 24, 1979. Please quote reference No. 3199. 208(A)

UNIVERSITY OF MALAWI CHANCELLOR COLLEGE

Applications are invited for the post of

LECTURER IN PHYSICS

Applicants should have a good honours degree in Physics or in Electronics and preference will be given to those with a higher degree and with some teaching and research or industrial experience. The appointee will be expected to teach at all levels of the five-year honours degree programme. Salary scale: Lecturer K3,500 to K6,600 per annum (£1 sterling equals K1.65). The British Government may supplement salary in range £3,450 to £3,654 per annum (sterling) for married appointee or £2,340 to £2,544 per annum (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. If no British Government supplement is available, the University may pay an addition of between K1,320 to K1,656 per annum (taxable in Malawi). Family passages; superannuation scheme; Gratuity 15 per cent to 25 per cent; biennial overseas leave; housing and various allowances. Detailed applications (two copies) with curriculum vitae and naming three referees to be sent to Registrar, University of Malawi, P.O. Box 278, Zomba, Malawi by May 5, 1979. Applicants resident in U.K. should send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 217(A)

UNIVERSITY OF MALAWI CHANCELLOR COLLEGE

Applications are invited for the post of

LECTURER IN ANALYTICAL CHEMISTRY

in the Department of Chemistry. Applicants should have an honours degree in Chemistry, and preferably a higher degree in analytical chemistry. They should also have had at least five years in the practice of analytical chemistry, preferably in industry. Salary scale: Lecturer K3,500 to K6,600 per annum (£1 sterling equals K1.65). The British Government may supplement salary in range £3,450 to £3,654 per annum (sterling) for married appointee or £2,340 to £2,544 per annum (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. If no British Government supplement is available, the University may pay an addition of between K1,320 to K1,656 per annum (taxable in Malawi). Family passages; superannuation scheme; Gratuity 15 per cent to 25 per cent; biennial overseas leave; housing and various allowances. Detailed applications (two copies) with curriculum vitae and naming three referees to be sent to Registrar, University of Malawi, P.O. Box 278, Zomba, Malawi by May 5, 1979. Applicants resident in U.K. should send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 213(A)

QUEEN MARY COLLEGE

University of London

PLANT BIOLOGY AND MICROBIOLOGY DEPARTMENT

Applications are invited for a

TEMPORARY LECTURESHIP

in Mycology or Fungal Plant Pathology for one year from September 1. Preference will be given to candidates with strong interests in Microbial Ecology. Salary on scale £3,883 to £7,754 per annum (under review plus £502 London Allowance. Please apply by letter, enclosing curriculum vitae, list of publications and names of three referees, to The Registrar (N), Queen Mary College, Mile End Road, London E1 4NS, not later than April 9. 214(A)

Science Research Council Daresbury Laboratory

COMPUTATIONAL SOLID STATE SCIENTISTS

The Theory and Computational Science Division of the SRC Daresbury Laboratory has vacancies for work in the computer simulation of solid state structures, both perfect and defective. It is intended that the programme of work be carried through in collaboration with ICI Corporate Laboratory, Runcorn and University groups principally at Oxford and University College London. The posts offered are as follows:

RESEARCH ASSOCIATE

This post is offered for a period of two years, on a salary scale of £3695 to £6216, depending on age, qualifications and experience. The successful man or woman, who will probably have a Ph.D. in Physics or Chemistry, will be expected to devote attention to the research aspects of the programme. The work will involve in part the construction and/or modification of large scale computer programs.

SCIENTIFIC OFFICER

This is a permanent position offered on a salary scale of £2839 to £4415, depending on age, qualifications and experience. The successful man or woman, who will have a good degree in Physics or Chemistry and possibly some post-graduate experience, will be responsible for providing support for University groups wishing to make use of the computer programs made available by the project, and will work in close liaison with the Research Associate mentioned above.

The laboratory has powerful computing facilities available, including an IBM 370/165 on site, and a link to two IBM 360/195 computers at the SRC Rutherford Laboratory.

The Theory and Computational Science Division is presently engaged on programmes in solid state and surface physics, the theory of molecular structure, X-ray crystallography and continuum processes in atoms and molecules.

Closing date: Tuesday 1st May 1979.

Further information can be obtained from Dr. V. R. Saunders,

Tel. Warrington 65000 (Ext. 204).

Please write or telephone Warrington 65000 (Ext. 467) for an application form, quoting Ref. No. DL/664/1 to:

The Personnel Officer

DARESBURY LABORATORY

Science Research Council

Daresbury, Warrington WA4 4AD

P96(A)

PURDUE UNIVERSITY RESEARCH ASSOCIATES THEORETICAL CHEMISTRY

Two openings exist for theoretical chemists to study molecular liquids and solutions with applications in organic chemistry. A Ph.D. in chemistry or physics and background in computing and molecular quantum or statistical mechanics are required.

Start anytime in 1979. Salary is \$12,000/year. Appointments are renewable.

Send vitae and names of references to: Prof. Wm. L. Jorgensen, Department of Chemistry, Purdue University, West Lafayette, Indiana 47907, U.S.A. An equal opportunity/affirmative action employer. W19(A)

M.R.C. CLINICAL RESEARCH CENTRE

(Northwick Park Hospital)

Watford Road, Harrow, Middx. HA1 3UJ

TECHNICIAN required in the Division of Communicable Diseases to participate in a research programme to investigate changes in tissue antigens in association with human cancers. The work will be carried out in an immuno-chemistry laboratory and is suitable for those interested in training in precise methods of immunochemical quantitations and in methodologies including the purification of antigens and antibodies, radioimmunoassays and immunofluorescence.

Qualifications: H.N.C. or science degree

Salary: within the range £3,615 to £5,034 inc. London weighting. Further details and application form from Mrs J. Tucker-Bull. Please quote reference 108/2/4070. Closing date April 27, 1979. 190(A)

**THE AUSTRALIAN NATIONAL UNIVERSITY
JOHN CURTIN SCHOOL OF MEDICAL RESEARCH
DEPARTMENT OF IMMUNOLOGY
PROFESSORIAL FELLOW**

Applications are invited for a position of Professorial Fellow in the Department of Immunology, John Curtin School of Medical Research. An appointment will be made to undertake research either in the field of Cancer Biology or in an area of Developmental and Reproductive Immunology.

Applicants interested in research into Cancer should have a comprehensive background in Cellular Immunology, particularly in relation to the response of the immune system to cellular antigens. Applicants who have worked in Reproductive Physiology or Developmental Biology should have an interest in foetal/maternal interactions and in the developmental aspects of the immune system.

Closing date: **31 May, 1979.**

**RESEARCH SCHOOL OF BIOLOGICAL SCIENCES
DEPARTMENT OF POPULATION BIOLOGY
POSTDOCTORAL FELLOW**

Applications for the above position which will become vacant in January 1980, are invited from biologists with interests in chromosome banding techniques, gel-electrophoresis or electron microscopy. The successful applicant will join a small group investigating the genetic basis and consequences of divergence via chromosomal rearrangements in natural populations of grasshoppers. Particular emphasis will be placed upon the study of patterns of recombination in experimental hybrids, both at the cytological and genic level. The karyotype of the species complex under investigation contains an array of markers, including pericentric chromosomal rearrangements, variation in heterochromatin distribution and biochemical polymorphisms and involves all members of the genome. It is ideally suited to an integrated analysis of the recombination process.

Closing date: **30 June, 1979.**

SALARY

Salary will be in accordance with qualifications and experience within the range: Professorial Fellow \$A30,713 per annum; Postdoctoral Fellow—a fixed point between \$A15,786 and \$A20,606 per annum. Current exchange rates are: \$A1 : 56p. : \$US1.13.

TERM OF APPOINTMENT

Professorial Fellow, until age 65 with the option of retiring at any time after age 60; Postdoctoral Fellow, one to two years. A shorter term may be negotiated for applicants on leave from other institutions.

OTHER CONDITIONS

Reasonable appointment expenses are paid. Superannuation benefits are available for applicants who are eligible to contribute. Assistance with housing is provided for an appointee from outside Canberra.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should obtain the further particulars from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF. 271(A)

**UNIVERSITY OF MALAWI
CHANCELLOR COLLEGE**

Applications are invited for the following posts in the DEPARTMENT OF BIOLOGY:—

1. **LECTURER IN ANIMAL PHYSIOLOGY/BIOCHEMISTRY.** The appointee will be required to teach comparative animal physiology and molecular and cellular biochemistry courses at upper levels within the degree programme. Research in a number of important areas is possible and encouraged but must be suited to facilities available in a developing country.

2. **LECTURER IN GENETICS.** The appointee will be required to teach introductory, population and molecular genetics within the degree programme. Research is encouraged and considerable opportunities exist in applied aspects of this field. Consequently, preference will be given to applicants with interests and experience in applied genetics.

3. **LECTURER IN POPULATION ECOLOGY.** The appointee will be required to teach both introductory and advanced topics in ecology within the degree programme. It is hoped that he/she will be able to contribute to the Country's active research in limnology and fisheries. Thus, preference will be given to applicants who have strong interests and experience in aquatic ecology—particularly fisheries.

4. **LECTURER IN VERTEBRATE ECOLOGY.** The appointee will be expected to develop a teaching and research programme in vertebrate zoology. Special interests within this area such as systematics, behaviour, and wildlife management will be an advantage.

Applicants must have a postgraduate degree in the relevant fields and previous teaching and research experience in a developing country will be an advantage. Highly qualified applicants may be considered at Senior Lecturer level.

Salary scales: Senior Lecturer K5,500 to K8,000 per annum. Lecturer K3,500 to K6,600 per annum (£1 sterling equals £1.65). The British Government may supplement salaries in range £3,450 to £4,128 per annum (sterling) for married appointees or £2,340 to £2,976 per annum (sterling) for single appointees (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. If no British Government supplement is available, the University may pay an addition of between K1,640 to K1,690 per annum for Senior Lecturers, K1,320 to K1,656 per annum for Lecturers (taxable in Malawi). Family passages; superannuation scheme; Gratuity 15 per cent to 25 per cent; biennial overseas leave; housing and various allowances. Detailed applications (two copies) with curriculum vitae and naming three referees to be sent to Registrar, University of Malawi, P.O. Box 278, Zomba, Malawi, by May 5, 1979. Applicants resident in U.K. should send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 216(A)

**UNIVERSITY OF
MELBOURNE
SENIOR LECTURESHIP
(LIMITED TENURE) IN
OVERSEAS AGRICULTURE
(ANIMAL PRODUCTION)
in the
SCHOOL OF AGRICULTURE
AND FORESTRY**

The University's General Development Grant is funding a new three-year project called "Training and Research in Overseas Agriculture". This project provides for the appointment until April 30, 1982 of a Senior Lecturer in Overseas Agriculture who would contribute directly to the project by giving lectures and conducting research in some aspects of Animal Production of importance in developing countries, and participate generally in research and teaching in Animal Production, thus allowing present members of staff to contribute to the new project. The appointee will teach in courses offered to undergraduate and postgraduate students in agriculture and veterinary science.

Applicants should hold postgraduate qualifications in Agricultural or Veterinary Science and should preferably have had experience in a developing country. Applicants with specialist qualifications and experience in Animal Nutrition or Animal Genetics will be particularly welcome.

SALARY: \$A21,180 to \$A24,657 per annum.

Enquiries to Professor N. M. Tulloh, in the University.

Further information regarding details of application procedure and conditions of appointment is available from the Staff Officer, University of Melbourne, Parkville, Victoria, 3052, Australia, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications close on April 22, 1979.

237(A)

**ROYAL POSTGRADUATE
MEDICAL SCHOOL
University of London**

CLINICAL PHARMACOLOGY

SCIENTIFIC OFFICER required to work on a number of research projects, centred on hypertension. The projects will include radioligand binding studies of receptors, and catecholamine turnover. The candidate should possess a degree or equivalent in a related subject. Experience in general biochemical techniques is required and a working knowledge of at least one of the projects is desired.

Salary on scale £3,887 to £6,169 a year, starting salary dependent on experience.

Application form and further particulars may be obtained from the Personnel Office, Royal Postgraduate Medical School, 150 Du Cane Road, London W12 0HS quoting reference number 20/103/N. 236(A)

**UNIVERSITY OF
DUNDEE
DEPARTMENT OF
PHYSICS**

Applications are invited for a two-year appointment as

RESEARCH ASSISTANT

to work in the above Department as a member of a research group directed by Professor W. E. Spear and concerned with the development of amorphous silicon devices.

The post would offer a challenging opportunity to someone with a good degree or professional qualification in physics or electrical engineering and with some research or development experience.

The starting salary will depend on qualifications and experience but could be in the region of £5,000 per annum (scale under review). The post is superannuable under U.S.S.

Applications in writing, quoting Reference EST/42/79J and containing a full curriculum vitae and the names of two referees, should be lodged by April 19 with The Secretary, The University, Dundee DD1 4HN. 197(A)

**UNIVERSITY OF
EDINBURGH
DEPARTMENT OF BOTANY
Applications are invited for a
POSTDOCTORAL
RESEARCH FELLOW**

to work with Dr. A. Trewavas on a three-year project supported by the A.R.C. The work will involve preparation of cDNA to cellulase mRNA to investigate the mechanisms of transcriptional control induced by auxin. Experience of techniques in this area of work would be an advantage but is not essential.

Salary is on the scale £3,883 to £6,555 per annum.

Applications (C.V. and two referees) may be made to Dr A. Trewavas, Department of Botany, The King's Buildings, Edinburgh, EH9 3JH, from whom further details may be obtained. Please quote Reference 5011. 115(A)

**LUDWIG INSTITUTE FOR
CANCER RESEARCH
(London Branch)**

(in association with the Royal Marsden Hospital and the Institute of Cancer Research, Sutton, Surrey)

UNIT OF MOLECULAR BIOLOGY
Applications are invited from suitably qualified and experienced

BIOCHEMISTS

to fill one or other of two appointments in the new Unit which will be established shortly under Dr P. S. Rudland. The principal focus of research will be on experimental aspects of mammary cancer.

For post (a), previous experience of protein and nucleic acid biochemistry is essential.

For post (b), previous experience of protein purification techniques and cell biology is essential.

Further particulars may be obtained from the address given below. Candidates for these appointments, which will commence in or before September 1979, should have gained appropriate postdoctoral experience which will be reflected by the salaries likely to be offered £5,129 to £6,080, plus London Weighting (equivalent to M.R.C. non-clinical Scientific Grade II). The appointments will be for an initial period of three years. University Superannuation Scheme available.

Apply with curriculum vitae and names of two referees to The Secretary, Ludwig Institute for Cancer Research (London Branch), The Haddow Laboratories, Royal Marsden Hospital, Belmont, Surrey SM2 5PX, before April 27, 1979. 166(A)

**UNIVERSITY OF BRISTOL
DEMONSTRATORSHIPS
IN GEOLOGY**

Applications are invited for two postgraduate University Demonstratorships in the Department of Geology. Successful applicants will be registered for a higher degree in one of the following research fields:

- (1) Metamorphic and geochemical studies in S.W. England or N. Norway.
- (2) Hydrogeology or engineering geology in S.W. England.
- (3) Submarine geology of the Western Approaches.
- (4) Lower Old Red Sandstone sedimentology, S. Wales.

The posts are tenable for three years from August 1, 1979. Duties will include twelve hours demonstrating per week. Salary £3,384 to £3,883 per annum (under review), with U.S.S. Superannuation. Preference will be given to applicants possessing a good honours degree with relevant experience and/or hold, or are expecting, a M.Sc. degree.

Applications, indicating field of research interest, to The Secretary, Department of Geology, Queen's Building, University of Bristol, University Walk, Bristol, BS8 1TR (from whom further particulars may be obtained), with names of two referees, by May 1, 1979. 242(A)

**UNIVERSITY OF
STIRLING
CHAIR OF EARTH
AND ENVIRONMENTAL
SCIENCE**

The successful applicant will lead teaching and research in a small but rapidly expanding team concerned with the earth's surface and man-environment relationships. He or she must be of high academic standing, with wide experience in the subject and broad interests so as to co-ordinate the activities of specialist staff and members of other departments contributing to the interdisciplinary teaching of Earth and Environmental Science. It is hoped the appointee will have a special interest in natural resources, land use or other applications of environmental science.

Further particulars are available from The University Secretary (N), University of Stirling, Stirling FK9 4LA, to whom applications should be made, together with the names of three referees, by April 27, 1979. 210(A)

**UNIVERSITY OF
NOTTINGHAM
SCHOOL OF AGRICULTURE
DEPARTMENT OF
APPLIED BIOCHEMISTRY
AND NUTRITION
POULTRY RESEARCH**

Opportunities exist in two areas: (i) food intake and the control of energy metabolism, and (ii) mechanism of the decline in shell quality with age, for research leading to higher degrees. Applicants must have, or expect to have, upper second class honours degrees, or better, in animal science (nutrition), physiology or biochemistry. Reply with a brief academic history and names of two referees to Dr K. N. Boorman, School of Agriculture, Sutton Bonington, Loughborough, Leics. LE12 5RD. 202(A)

**MEDICAL RESEARCH
COUNCIL
LABORATORY ANIMALS
CENTRE
TECHNICIAN**

There is a vacancy in the Genetics Department for a technician to assist in the institution of systems of genetic monitoring of small laboratory animals. Experience in immunological and electrophoretic techniques would be an advantage. An H.N.C. or equivalent qualification is essential.

Incremental salary in the range £3,261 to £4,680 plus £354 London Weighting. Contributory superannuation scheme.

Applications to The Chief Technician's Office, Laboratory Animals Centre, Woodmansterne Road, Carshalton, Surrey SM5 4EF. 244(A)

**THE
QUEEN'S UNIVERSITY
OF BELFAST
POSTDOCTORAL
FELLOW
IN CHEMISTRY**

Required to work in collaboration with Dr D. R. Boyd on the synthesis of optically active metabolites of polycyclic aromatic hydrocarbons. The post is available for one year from October 1, 1979 or such other date as may be agreed.

Salary range £3,885 to £4,385 per annum.

Applications with curriculum vitae and the names and addresses of two referees should be addressed to the Personnel Officer, The Queen's University of Belfast BT7 1NN, Northern Ireland. 198(A)

NUCLEAR STRUCTURE PHYSICISTS

The Daresbury Laboratory, an establishment of the Science Research Council situated in the north Cheshire countryside, has 2 vacancies for Experimental Nuclear Structure Physicists in the Nuclear Structure Division.

The successful men or women will be involved in the research programme on a 30 MV tandem electrostatic accelerator at present under construction.

The duties of the posts will be to carry out research in conjunction with university users on the Nuclear Structure Facility. In addition they will provide the overall co-ordination and scheduling of the scientific programme, organisation of effort within the Laboratory for supporting the programme, and will assess the future needs for instrumentation and other facilities.

These posts require scientists with a good knowledge of either nuclear structure physics or of a related field, so that a high level of expertise in nuclear structure physics could be gained rapidly. Successful candidates will have experience in designing and using scientific equipment, and preferably some experience in the organisation of the work of teams of physicists engaged on experiments.

Applicants should have several years of experience and possess good academic qualifications, preferably a good honours degree in a relevant discipline. Appointments will be made, according to age, experience and qualifications, on the following scales:

Higher Scientific Officer £4,101 - £5,448 (under review)

There is a non-contributory superannuation scheme, a generous leave allowance and a flexible working hours scheme.

Closing date: 1st June 1979

Please write, or telephone Warrington 65000 Ext. 467 for an application form quoting reference No. DL/666/T to:

The Personnel Officer

DARESBURY LABORATORY
Science Research Council
Daresbury, Warrington WA4 4AD

194(A)

**UNIVERSITY OF WARWICK
LECTURESHIP IN
ENVIRONMENTAL
SCIENCES**

Applications are invited for a Lectureship in the Department of Environmental Sciences, tenable from October 1, 1979. The appointment will be the fifth academic post in a Department whose research largely concerns microbial ecology and biochemistry and biodegradation processes. Applicants should have interests in these or related fields. Initial salary within the first four points of the Lecturer scale: £3,883 to (£4,631) to £7,754 per annum (under review), with superannuation benefits. Further particulars and application forms from the Academic Registrar, University of Warwick, Coventry CV4 7AL, quoting Ref. No. 34/A/79. Closing date for receipt of applications is April 27, 1979. 231(A)

**THE UNIVERSITY
OF MANITOBA**

The University of Manitoba invites applications for the position of Professor and Head of the Department of Statistics. Currently there are twelve faculty members in the Department which offers undergraduate and graduate programmes, and the laboratories and facilities provide a stimulating environment for research and teaching.

Salary will be appropriate to the qualifications of the appointee. The 1978-79 floor for full professors is \$27,540.

Canadian citizens, landed immigrants and others eligible for employment in Canada at the time of application are especially encouraged to apply.

Applications should be made as soon as possible, with a deadline of June 15, 1979, giving curriculum vitae, publication list and names of three referees to: Dr R. D. Connor, Dean, Faculty of Science, University of Manitoba, Winnipeg, Manitoba. W20(A)

**UNIVERSITY OF
ST. ANDREWS
DEPARTMENT OF
ZOOLOGY**

Applications are invited for a Lectureship in the Department of Zoology tenable from September/October 1979. The successful candidate will be a member of the Department of Zoology, with research facilities either at the Gatty Marine Laboratory or the Zoology Department, dependent on the candidate's own research. Preference will be given to an experimental biologist.

Salary at appropriate scale £3,883 to £7,754 (under review), starting salary not above £5,604, plus U.S.S.

Applications should preferably be in typewritten names of three referees to: The Personnel Officer, University of St. Andrews, St. Andrews, Fife, KY16 9SS. 198(A)

**THE UNIVERSITY
OF LEEDS**
DEPARTMENT OF PLANT
SCIENCES

Applications are invited for a
temporary post of
LECTURER

with a special interest in
AGRICULTURAL CHEMISTRY
in the above Department, available
from October 1, 1979. The
appointment will be made for a
fixed term of three years.

Candidates should have a good
background in chemistry and phys-
ics, preferably with an under-
standing of the function and fate
of pesticides. However, candidates
with other interests should not be
deterred from applying. The duties
of the successful candidate will in-
clude teaching agricultural chem-
istry to students in the agricultural
sciences and botany. He/she will
also be expected to develop an
active research programme. The
department has good research
facilities.

Salary on the scale for lecturers
£3,883 to £7,754 (under review),
according to age, qualifications and
experience.

Application forms and further
particulars may be obtained from
the Registrar, The University,
Leeds LS2 9JT, quoting reference
number 53/10D. Closing date for
applications April 27, 1979.

266(A)

**UNIVERSITY COLLEGE
CARDIFF**

Applications are invited for the
post of

RESEARCH ASSISTANT

in the Department of BIO-
CHEMISTRY. The successful candi-
date should have a good Honours
degree in biochemistry or a related
subject and will work with Dr J. Kay
on chicken papain as a rennet substi-
tute with studies on its production,
stability and activity. The project will
involve techniques such as enzyme
purification, affinity chromatography,
milk clotting assays and protein
structural investigations.

The appointment which will be for
one year, in the first instance, renew-
able for a further two years, is
financed by a grant from the Agricul-
tural Research Council. Salary range
£3,384 to £3,883 (under review).

Applications (two copies), including
a curriculum vitae together with the
names and addresses of two referees,
should be forwarded to the Vice-
Principal (Administration) and
Registrar, University College, P.O.
Box 78, Cardiff CF1 1XL. Closing
date April 30, 1979. Reference 1744

199(A)

**ASSISTANT PROFESSOR
DIRECTOR
INSTITUTE OF
MARINE SCIENCE
UNIVERSITY OF ALASKA**

The University of Alaska, Fair-
banks, invites applications for the
position of Director, Institute of
Marine Science and Division of Marine
Science. Applications should be sent
to the Registrar, University of Alaska,
Fairbanks, Alaska 99775. Further par-
ticulars and application forms may be
obtained from the Registrar, University
of Alaska, Fairbanks, Alaska 99775.

UNIVERSITY OF LEEDS
DEPARTMENT OF
CARDIOVASCULAR STUDIES
TECHNICIAN IN CHARGE

required to supervise cardiological
physiological techniques. The post
involves administration, quality
control, training of staff, and co-
ordination of routine diagnostic
technical investigations in two hos-
pitals, and requires an ability to
control a large technical staff (30
plus technicians) and be responsible
to hospital consultants. Experience
in the technique of cardiological
investigation is essential. Prior
enquiry to the department is en-
couraged. The level of qualification
looked for is H.N.C. or equivalent,
together with substantial relevant
experience.

Salary is on the scale £5,085 to
£5,517 (Grade 8B). Salaries are
presently under review.

Applications to: Professor R. J.
Linden, Department of Cardio-
vascular Studies, New Medical
School, University of Leeds, Leeds
LS2 9JT. 260(A)

**ASSISTANT:
STRUCTURAL GEOLOGY,
ETH ZURICH**

Applications are invited for a pos-
ition as Assistant to Professor Ramsey
to set up a laboratory for the study of
model simulations of tectonic struc-
tures. Applicants should hold a Ph.D.
or equivalent degree, and have a sound
background in computer techniques.
Some previous experience of physical
and numerical modelling would be
useful. The position starts September
1, 1979, initially for three years, with
the possibility of extension beyond this
period.

Further information in the nature
of the work, and the research activities
of the structural geology group will be
sent on request. Applicants should
send a curriculum vitae, and the
names of two referees to Professor
J. G. Ramsay, Geol. Inst. ETH, ETH-
Zentrum, 8092 Zurich. 28(A)

**UNIVERSITY OF
NEWCASTLE UPON TYNE**
CHAIR OF
INORGANIC CHEMISTRY

Applications are invited for the
Chair of Inorganic Chemistry from
candidates whose teaching and research
interests lie broadly within that field.
The appointment carries with it the
Headship of the Department for an
initial period of five years. Salary will
be on the professional range. Member-
ship of a University superannuation
scheme will be required.

Further particulars may be obtained
from the Deputy Registrar, University
of Newcastle upon Tyne, 6 Kensington
Terrace, Newcastle upon Tyne NE1
7RU, with whom applications (15
copies) giving the names of not more
than three referees, should be lodged
not later than April 20, 1979. (Appli-
cants from outside the British Isles
may submit one copy only.) 254(A)

**THE UNIVERSITY
OF MANCHESTER**
DEPARTMENT OF
GEOGRAPHY

Applications are invited for a two-
year RESEARCH ASSISTANT post
concerned with glacioclimatological
studies in Norway and Switzerland.
Applicants should hold, or expect this
summer to obtain, a first or upper
second class degree in earth sciences,
physics or chemistry. Opportunities to
register for a higher degree. Post
tenable from October 1. Salary range
per annum £3,384 to £3,634. Particu-
lars and application forms (returnable
by April 9) from the Registrar, The
University of Manchester, M13 9PL.

Computer Manager

The Public Health Laboratory Service Board invites
applications from suitably qualified candidates with
enthusiasm and drive for the position of Manager to
take charge of a newly-formed Data Processing Unit.

The Board provides a microbiology service at 52
laboratories throughout England and Wales, at the
Central Laboratory, Colindale, N.W.9, and from
April 1, 1979, at the new Centre for Applied Micro-
biology & Research, Porton Down, Wiltshire. A
number of computer projects already operate and these
are to be brought under centralised control together
with future developments. A CTL computer is now
being installed at Porton Down.

The Manager will be responsible for planning the
development of a coherent, organised service. He/she
will be based at Colindale though at first, during the
commissioning and programming of the new computer,
much time will be devoted to the unit at Porton Down.

The successful candidate is likely to be a graduate
with sound experience of modern computing methods.
He/she, while responsible to the Board's Headquarters
officers, will work with senior scientific and medical
staff of the different units.

The appointment will be under N.H.S. terms and
conditions of service with a salary on scale 23, £6,955
to £8,423 plus £354 London Weighting.

A copy of the job description may be obtained from
Dr R. A. Bassett, P.H.L.S. Board, 61 Colindale
Avenue, London NW9 5EQ (Tel: 01-200 1295) to
whom applications with full career
details and names and addresses of
three referees should be sent by April
23, 1979. 189(A)

**PH
LS**

**Public Health Laboratory
Service Board**

AGRICULTURAL RESEARCH COUNCIL

Institute for Research on Animal Diseases

SCIENCE COMPUTER PROGRAMMER

required to join Statistics Section involved in the development of database
management and statistical computer systems. The successful applicant
will work with statisticians in the section and collaborate with research
staff. The Institute has remote links to an ICL 4/70-72 computer at
Rothamsted Experimental Station.

Qualifications: degree, HNC or equivalent, with experience in computer
science, mathematics or statistics, at least 5 years' relevant experience
for appointment to HSO.

Salary scales: Scientific Officer £2,839 per annum to £4,415 per annum
or Higher Scientific Officer £4,101 per annum to £5,448 per annum
depending on qualifications and experience. Non-contributory pension
scheme.

Application forms:

Secretary,

Institute for Research on Animal Diseases,
Compton, Nr. Newbury, Berks. RG16 0NN.
Quoting Ref: 346.

ratory scientific officer to assist
genetic and cell biology work
involving tissue culture. Candidates
with relevant experience preferred. Ap-
plications should be sent to:
Administrative Assistant, Paediatric
Research Unit, The Prince of
Wales Research Laboratories, Guy's Hosp
Medical School, London Bridge, S

MEDICAL RESEARCH COUNCIL

NATIONAL INSTITUTE FOR MEDICAL RESEARCH

Applications are invited for a three-year POSTDOCTORAL appointment in the DIVISION OF PARASITOLOGY, available from October 1, 1979. The successful candidate will be required to develop monoclonal antibody techniques for the analysis of antigens of malaria parasites. There is particular interest in parasite antigens present in the erythrocytic membrane, and in isoantigenic changes in this membrane resulting from the presence of the parasite. Experience in monoclonal antibody techniques and/or immunochemistry or membrane biochemistry desirable.

The appointment will be in the salary range £4,408 to £6,080 per annum according to age and qualifications, plus £450 per annum London Allowance. Superannuation provision.

Applications, giving details of qualifications, experience and the names of two professional referees, should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA before April 30, 1979, quoting reference P/1. 275(A)

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL

in association with Chelsea College and the Royal Dental Hospital of London School of Dental Surgery (University of London)

LECTURER/SENIOR LECTURER IN BIOCHEMISTRY

Particulars available from the Establishment Office, St. George's Hospital Medical School, Cranmer Terrace, London SW17 0RE, to whom applications, with the names of three referees, must be sent to arrive by April 23, 1979. 245(A)

UNIVERSITY OF ABERDEEN CHAIR OF ZOOLOGY

Applications are invited for the above Chair which falls vacant on January 1, 1980. Preference may be given to Zoologists with experience in the experimental laboratory approach to animal biology. The successful candidate may be called upon in due course to exercise the responsibilities of Head of the Department of Zoology.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (two copies) should be lodged by April 30, 1979. 223(A)

WELSH PLANT BREEDING STATION UNIVERSITY COLLEGE OF WALES, ABERYSTWYTH N.E.R.C.

RESEARCH STUDENTSHIP

Applications are invited for a N.E.R.C. Research Studentship tenable for three years from October 1979 on ONE of the following research topics:

1. Variation within and between grass species in reaction to environmental stress (Supervisor: Dr A. H. Charles).

2. Ecological genetics of natural populations of perennial ryegrass (Supervisor: Dr M. D. Hayward).

The candidate, who should possess or expect to gain a good Honours degree in a relevant discipline, will be registered with the University of Wales for a higher degree.

Applications, including the names of two referees, should be sent before April 18 to The Secretary, Welsh Plant Breeding Station, Plas Gogerddan, Aberystwyth, Dyfed SY23 3EB from whom further particulars can be obtained. 238(F)

UNIVERSITY OF NOTTINGHAM

RESEARCH STUDENTSHIP

in Laser Spectroscopy of short-lived molecules

Applications are invited for a three-year Research Studentship tenable from October 1, 1979. The successful candidate will be expected to read for a Ph.D. The research project involves laser spectroscopy of gaseous molecular ions, and laser-induced reactions of ions. Emphasis will be placed on problems of astrophysical and atmospheric interest. Applicants should possess or expect to obtain a 1st or upper second class Honours degree in Chemistry or Physics, and should write to Dr P. J. Sarre, Department of Chemistry, University of Nottingham, University Park, Nottingham, by April 20, 1979. 207(F)

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF PHYSIOLOGY AND ENVIRONMENTAL STUDIES SCHOOL OF AGRICULTURE,

SUTTON BONINGTON, LOUGHBOROUGH, LEICS.

N.E.R.C.

RESEARCH STUDENTSHIP

Applications are invited from suitably qualified students for a N.E.R.C. studentship tenable from October 1st 1979. Candidates should have or expect to receive at least an Upper Second Class Honours degree in the Plant Sciences. The project is concerned with plant adaptation and colonisation in relation to nitrogen supply. The work will be supervised jointly by Professor W. J. Whittington and Dr G. C. Blackwood from whom further details can be obtained at the address given above. 201(F)

UNIVERSITY OF LONDON KING'S COLLEGE DEPARTMENT OF ZOOLOGY

N.E.R.C. STUDENTSHIP

Applications are invited from biologists holding or expecting to obtain a first class or upper second class honours degree for a N.E.R.C. Postgraduate studentship for research on:

(a) The epidemiology of rodent pipriplasmiasis (Professor F. E. G. Cox).

(b) The parasitic relationship between gall forming arthropods and their tree hosts (Dr B. D. Turner).

Further particulars and application forms may be obtained from the Secretary, Department of Zoology, King's College, Strand, LONDON WC2R 2LS, quoting reference 191667/N. 182(F)

UNIVERSITY OF YORK

DEPARTMENT OF BIOLOGY

POSTGRADUATE STUDENTSHIP

Applications are invited for a N.E.R.C. supported postgraduate studentship in the Department of Biology. One research area for which the studentship may be awarded is the investigation of a B-chromosome polymorphism in populations of *Allium schoenoprasum*.

Applicants should have, or expect to obtain, a first or upper second class honours degree.

Further details are available from Dr S. M. Bougourd, Department of Biology, University of York, Haslington, York YO1 5DD. 255(F)

WELSH PLANT BREEDING STATION UNIVERSITY COLLEGE OF WALES, ABERYSTWYTH A.R.C.

RESEARCH STUDENTSHIP

Applications are invited for an A.R.C. Research Studentship tenable for three years from September/October 1979 on ONE of the following research topics:

1. Competitive interactions in herbage crops (Supervisor: Dr J. Hill).

2. Cold hardiness in forage grasses (Supervisor: Dr C. F. Eagles).

The candidate, who should possess or expect to gain a good Honours degree in a relevant discipline, will be registered with the University of Wales for a higher degree.

Applications, including the names of two referees, should be sent before April 16, 1979 to The Secretary, Welsh Plant Breeding Station, Plas Gogerddan, Aberystwyth, Dyfed SY23 3EB, from whom further particulars can be obtained. 239(F)

ASSISTANTSHIPS

THE UNIVERSITY OF SHEFFIELD DEPARTMENT OF MICROBIOLOGY

POSTDOCTORAL

RESEARCH ASSISTANTSHIP

Applications are invited from men and women for a Postdoctoral Research Assistantship financed by the S.R.C. to work on the mechanism of methanol assimilation in yeasts, involving isotopic work with whole cells and purification and study of enzymes. Applicants should possess or expect soon to possess a Ph.D. in microbiology or biochemistry. Tenable immediately until March 31, 1982 but consideration will be given to applicants expecting to complete their Doctorates by October 1979. Salary up to £4,382 a year on Range 1A. Particulars from Professor J. R. Quayle, Department of Microbiology, University of Sheffield, Sheffield S10 2TN, to whom applications, quoting two referees, should be sent by April 9, 1979. Quote ref: R 268/G. 268(P)

STUDENTSHIPS

THE UNIVERSITY OF ASTON IN BIRMINGHAM

DEPARTMENT OF GEOLOGICAL SCIENCES

N.E.R.C. RESEARCH STUDENTSHIPS

Applications for the above studentships leading to a Ph.D. degree are invited in the following fields:

- Structure, stratigraphy and litho-geochemical haloes around mineral deposits at Parye Mountain, Anglesey (CASE Award).
- Metal sulphide ores—studies of the rates and mechanisms of exsolution processes.
- Microstructure and microchemistry of heterogeneous meteorites (CASE Award).
- Engineering geological mapping in the Birmingham area.

Applications and requests for further details to be sent to Professor D. D. Hawkes, Department of Geological Sciences. 262(F)

The University of Aston in Birmingham

Gosta Green

Birmingham B4 7ET

MEDICAL RESEARCH COUNCIL

Clinical and Population Cytogenetics Unit

Applications are invited for graduates with good honours degrees and from prospective graduates for

MRC RESEARCH STUDENTSHIPS

that have been requested for October 1979. Awards will be in the fields of meiosis immunoglobulin production *in vitro* and computer pattern recognition. Studentship will be for a maximum period of 3 years and successful applicants will be expected to register for the degree of Ph.D. at the University of Edinburgh.

Application details and summaries of the projects are available from the Administrative Officer, MRC Clinical and Population Cytogenetics Unit, Western General Hospital, Crewe Road, Edinburgh EH4 2XU. 279(F)

ASSISTANTSHIPS—cont.

UNIVERSITY OF DURHAM
DEPARTMENT OF CHEMISTRY
Applications are invited for chemists
or chemical physicists for an
**S.R.C. POSTDOCTORAL
SENIOR RESEARCH
ASSISTANTSHIP**

for sixteen months from as soon as possible, to work in collaboration with Dr J. Yarwood on the interaction and dynamics of hydrogen bonded systems in the liquid phase. These studies, which include infrared, far-infrared, Raman and neutron scattering studies are also supported by a N.A.T.O. research grant and would be carried out at Durham, the Technical University, Braunschweig and at A.E.R.E. Harwell. Some experience in one branch of molecular spectroscopy is essential and an interest in the chemical physics of molecular motions and interactions in the liquid phase would be an advantage.

Initial salary £3,883 or £4,133 per annum on National Research Range 1A plus superannuation.

Applications (three copies) naming three academic referees should be sent by April 18, 1979, to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars can be obtained

278(P)

UNIVERSITY OF BRISTOL
DEPARTMENT OF
ZOOLOGY
**RESEARCH ASSISTANTSHIP
IN REPRODUCTIVE
NEUROENDOCRINOLOGY**

Applications are invited for a post-graduate research assistantship to work with an established research group on a project associated with the neural and neuroendocrine basis of seasonal breeding cycles in mammals. The post, which is financed by a grant from the Agricultural Research Council, is available from October 1979 and will last for three years. Candidates should have, or expect to obtain, a first or upper second class Honours degree. The commencing salary (scale 1B) will be £3,384 per annum plus U.S.S. (scale under review).

Further information may be obtained from Professor B. K. Follett, Department of Zoology, University of Bristol, Woodland Road, Bristol RS8 1UG. Applications, including the names and addresses of two referees, should be sent to him by April 13, 1979.

240(P)

UNIVERSITY OF
LEICESTER
DEPARTMENT OF GEOLOGY
**POSTGRADUATE
RESEARCH ASSISTANTSHIP
IN GEOPHYSICS**

Applications are invited for a post-graduate appointment to work on the development of model seismology for undergraduate teaching. The project will entail the development of a model for the examination of seismic wave propagation through simulated geological structures using seismic reflection and refraction techniques. It will also involve the development of processing programmes demonstrating procedures used in industrial and academic seismic data processing schemes.

The post is available for six months commencing July 1, 1979 and would suit a geophysics or physics graduate with a good honours degree, who is practically minded and has a strong interest in computing.

SALARY RANGE £3,884 to £4,133 per annum.

Applications (one copy) with curriculum vitae and the names of two referees should be sent to Dr P. K. H. McIntyre, Department of Geology, University of Leicester, Leicester LE1 7RH, before May 31, 1979.

Further particulars are available

UNIVERSITY OF
NOTTINGHAM
SCHOOL OF AGRICULTURE
SUTTON BONINGTON
LOUGHBOROUGH

**TWO
RESEARCH ASSISTANTSHIPS**

tenable from October exist in the Department of Agriculture and Horticulture. The work is supported by the Agricultural Research Council for a three-year period on the following topics:

1. Puberty and reproduction in the gilt (supervised by Dr D. J. A. Cole).
2. Voluntary feed intake in the growing pig (supervised by Dr D. J. A. Cole and Professor D. Lewis).

Candidates will have the opportunity to register for a higher degree. Salary £3,384 to £3,883 per annum.

Applications including a full curriculum vitae and the names and addresses of two referees should be sent to Dr D. J. A. Cole at the School as soon as possible 200(P)

COURSES

**SOUTH EAST THAMES
REGIONAL HEALTH
AUTHORITY**

**in co-operation with the
UNIVERSITY OF SURREY**

The Authority offers special training posts as Basic Grade Biochemists with the opportunity to study for an M.Sc. in Clinical Biochemistry.

Posts are available from October 1979 for a two year sandwich M.Sc. Course at the University. In the case of fresh graduates, a good honours degree, e.g. Biochemistry or Chemistry (or its equivalent) is essential.

During the parts of the course spent away from the University, students must work in a specified hospital laboratory in the area of the Authority. The certificate of proficiency will normally be issued to candidates successfully completing the two year course.

University application form together with the postgraduate prospectus, and separate Regional Health Authority application form and sponsorship details are obtainable from the Academic Registrar, University of Surrey, Guildford. Applicants must give past examination grades.

Closing date for receipt of applications. April 23 (Ref 953). 265(D)

SYMPOSIA

**FEBS SYMPOSIUM
ON DNA**

Liblice, near Prague,

Czechoslovakia

24-29 September 1979

Topics: Recombinant molecules of DNA; DNA-protein interactions, DNA recombinations *in vivo*, DNA repair

Information from Drs S. Zadravil and J. Sponar, Institute of Organic Chemistry and Biochemistry, Czechoslovak Academy of Sciences, Flemingova nám.2, 166 10 Prague 6, Czechoslovakia

The closing date for applications is May 15, 1979 250(M)

FELLOWSHIPS

**UNIVERSITY OF
EDINBURGH**

Applications are invited for the William Gordon Sogge Brown Research Fellowship in Mathematics, tenable in the University of Edinburgh for one or two academic years from October 1, 1979. Stipend is in the Research Salary range 1A, which is equivalent to the Lecturer's scale. Applications (before April 30, 1979) should be addressed to Professor A. G. Mackie, Department of Mathematics, University of Edinburgh, James Clerk Maxwell Building, King's Buildings, Mayfield Road, Edinburgh EH9 3JZ, U.K., from whom further particulars can be obtained. Please quote Ref: 237(F)

UNIVERSITY OF
SOUTHAMPTON
SCHOOL OF BIOCHEMICAL
AND PHYSIOLOGICAL
SCIENCES
**POSTDOCTORAL
RESEARCH FELLOWSHIP
PHYSIOLOGY/
PHARMACOLOGY**

Applications are invited for a POSTDOCTORAL RESEARCH FELLOWSHIP IN PHYSIOLOGY. Candidates should have a scientific and/or medical qualification and research experience, preferably with publications, in an aspect of Physiology and/or Pharmacology. It would be helpful if the applicant had particular interest in cardiovascular and/or renal physiology and in the mechanism of action of angiotensin. The successful applicant will join research teams actively involved in transport studies renal physiology and hypertension and/or studies into the physiological effect of burns. The Research Fellow may be called upon to participate in research supervision and from time to time in a small amount of teaching of courses in both the Faculty of Science and in the Faculty of Medicine. Excellent facilities for research in all aspects of physiology, pharmacology, histology and histochemistry are available. The appointment is for one year in the first instance, is renewable and will commence as soon as possible. Further particulars are obtainable from Professor K. A. Munday.

Salary Range: £3,883 to £4,882 per annum (under review). USS benefits. Initial placing according to qualifications and experience. Applications giving date of birth, curriculum vitae and the names and addresses of three referees, should be sent by April 20, 1979 to: Mrs P. Vaughan-Smith, The University, Southampton SO9 5NH, quoting reference 1061/R.

162(E)

UNIVERSITY OF
GLASGOW
**RESEARCH FELLOWSHIP
IN
SOLID STATE PHYSICS**

Applications are invited for a University Postdoctoral Research Fellowship in experimental Solid State Physics. The current research interests of the Solid State group are the Physics of Amorphous Materials and Electron Physics. In the case of the latter subject the group has just received a large S.R.C. grant to purchase a U.H.V. Scanning Transmission Electron Microscope.

The Fellowship is tenable for up to three years. The initial salary will be from £3,883 to £5,367 per annum depending on age and experience, on Range 1A of the salary scales for Research and Analogous Staff (under review). Superannuation benefits will apply.

Applications stating age, academic qualifications, research experience and the names of two referees should be submitted not later than April 30, 1979, to Professor J. C. Gunn, Department of Natural Philosophy, University of Glasgow, Glasgow G12 8QQ, from whom further details of the research work of the Solid State Physics group may be obtained.

In reply please quote Ref. No. 4408/M. 263(E)

**THE UNIVERSITY
OF MANCHESTER**

Applications are invited from graduates or those expecting to graduate in 1979 for:

**RESEARCH STUDENTSHIP
IN SCIENCE AND MEDICINE**

Value as for S.R.C. studentships, renewable after first year.

Particulars and application forms (returnable by June 1) from the Registrar, The University, Manchester M13 9PL. Quote ref: 55/79/N. 106(F)

UNIVERSITY OF
GLASGOW
**RESEARCH FELLOWSHIP
IN PHYSICS**

Applications are invited for a number of University Postdoctoral Research Fellowships in Physics from persons whose research interests lie in the following fields:

Experimental Gravitation (Grav Wave Detection), High Energy Physics, Nuclear Structure, Theoretical Plasma Physics, Nuclear Structure.

The Fellowships are tenable for up to three years from October 1, 1979. The initial salary will be from £3,367 to £5,367 per annum depending on age and experience on Range 1A of salary scales for Research and Analogous Staff (under review). Superannuation benefits will apply.

Applications stating age, academic qualifications, research experience and the names of two referees should be submitted not later than April 1979, to Professor J. C. Gunn, Department of Natural Philosophy, University of Glasgow, Glasgow G12 8QQ, from whom further details of the research work of the Department may be obtained.

NICHOLAS COPERNICUS

VOLUME II ON THE REVOLUTIONS

AN ENGLISH TRANSLATION BY

EDWARD ROSEN

Nich Copernicus

It is nearly 500 years since Nicholas Copernicus, the father of modern physics, dedicated to His Holiness Pope Paul III, his theories on physics in *De Revolutionibus Orbium Coelestium*.

Now for the modern academic, unversed in mediaeval Latin, Professor Rosen has produced a new translation, together with a detailed commentary on the complete Latin text.

This is the 2nd volume in a planned 3-volume set of the complete works of Copernicus organised by the Polish Academy of Sciences. Printed and bound to a very high standard, it is a work of great scholarship and art in its own right, and a fitting companion to Volume I, the full-colour facsimile edition published in 1972.

Points of view

At Miles Research we are continually developing reagents for better visualization of specific antigenic substances in cells and tissues. Our extensive line includes reagents suitable for a broad range of immunohistochemical techniques used in the clinical and research laboratory.

Immunofluorescent: Localization of gonadotropin receptors in ovarian cells by indirect immunofluorescence. Granulosa cells were incubated with human chorionic gonadotropin (HCG) and subsequently with anti-HCG, followed by fluorescein-conjugated second antibody. Discrete patches of fluorescence (arrowheads) indicate the hormone receptor sites at the circumference of the cell. (Amsterdam A, et al: *Proceedings of the Workshop on Follicular and Corpus Luteum Function*, New York, Plenum, in press.)

Immunoferritin: Electron microscopic localization of the nicotinic acetylcholine receptor in membrane vesicles from *Torpedo California* (electric ray) organ tissue with Fab₂ fragments of antiacetylcholine receptor and subsequently with ferritin-conjugated second antibody. The section was stained for 20 sec with lead citrate. Ferritin molecules (arrowheads) cover the outer surface of closed membrane profiles. (Tarrab-Hazdai R, et al: *Proc Natl Acad Sci USA* 75 2497-2501, 1978.)

Immunoperoxidase: Localization of neuraminidase in the crypt bases of polymorphs in the stroma of human small intestine. The tissue section was incubated with antineuraminidase, followed sequentially with second antibody and peroxidase antiperoxidase. Peroxidase was demonstrated with 3, 3', 5, 5' diaminobenzidine. (Courtesy of MJ O'Brien, G.I. Research Laboratory, Mallory Institute of Pathology, Boston.)

The Miles Research Products line of conjugated antisera—designed to meet the needs of the biomedical research scientist or the clinical scientist in cytology, serology, immunology, microbiology, and histology—is

Comprehensive...

Offers antisera for visualization of antigenic substances through UV and/or visible light microscopy, photometry, and electron microscopy.

Extensive...

Includes FITC (fluorescein) conjugates, ferritin conjugates, alkaline phosphatase conjugates of antisera to human proteins, animal proteins, and second antibodies... plus an exceptionally wide selection of peroxidase conjugates for light or electron microscopy.

Practical...

Each vial of finished product is accompanied by a Product Credential giving general and lot-specific product information, antibody titer, and label-to-protein ratio.

Conjugated Antisera from Miles Research Products.

Martian storm system

An unconventional balance with an extra measure of accuracy

Mettler DeltaRange breaks through the boundaries that used to restrict the capacity/accuracy ratios of conventional weighing instruments. And Mettler PC electronic top-loading balances are equipped with this new *Mettler DeltaRange* feature.

Just press the control bar of the Mettler PC4400, for example, and you get a 400 g fine range with readings that are 10 times as accurate as those in the coarse range. And you can do it as often as you wish, at any point of the entire weighing range. That is to say, whenever and wherever a 0.01 g readability is needed. On a balance that has a capacity of no less than 4000 g!

In practice, this means that you can use a heavy container to accurately weigh in as many components as you want. Or that you can weigh one time on a lightweight paper, the next time into a heavy recipient; both times with results that are readable to the second decimal place.

To learn more about the many things your Mettler PC balance can do for you with outstanding speed and precision, send for our detailed brochure. It's an eye-opener.

Cover picture

The Viking Orbiter 1 spacecraft has provided the first photographs of a cyclone system on Mars. Data collected by IR mapping sensors suggest that the clouds consist mainly of water vapour rather than the expected CO₂ ice particles. Details of the martian meteorology observations are reported on page 531. Wind effects on Mars as determined from Viking Orbiter and Lander results are detailed on page 533.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258,1 (1975) and 264, v, 11 Nov. (1976)

Antigen-specific suppressive factor produced by a transplantable I-J bearing T-cell hybridoma	M. Taniguchi, T. Salto and T. Tada	555

A quiet case for European science

WHATEVER issues the forthcoming election in Britain brings up, two things are reasonably certain: that the nation's place in the European Economic Community will be widely discussed and that science and technology policy will not. But, argues André Danzin in a newly published book *Science and the Second Renaissance of Europe* (Pergamon), the future of Europe is so much bound up in science and technology that if the public were kept adequately informed "scientific and technical policy would be expressed in terms of electoral concern".

What are we to make of Western Europe? Danzin, who is chairman of the European Committee for Research and Development (CERD) an advisory committee of twenty-one individuals, paints a very realistic picture of the deep problems, but also the immense potential of the region. The real resource is people and their cultural identity, but in recent years, limitations on space, materials, energy and money have dimmed the spirit. By almost any criterion, the nine of the EEC have failed to keep pace with the United States or Japan. (Danzin is excessively scrupulous about regarding the EEC as an entity, and almost never talks about individual nations; hence the economic and growing scientific strength of West Germany is neutralised by poor performances elsewhere in the community.)

He does not believe there is evidence that Europe is falling behind in its possession of knowledge; it is the "lack of concern" that is hobbling progress. And for Danzin, progress is undoubtedly closely tied for the foreseeable future to science and technology, and more specifically to the world of information. He shows a striking graph (admittedly from an American source) which demonstrates the colossal recent growth in numbers of those who could be said to be working in 'information' rather than agriculture, industry and personal services. It is estimated that more than 50% of the working population is now engaged in acquiring, storing, processing and transmitting information, or in working in allied support industries. And there is no sign that the trend which has lifted this figure from 15% to 50% in thirty years is yet over.

If there is every sign that information is becoming such an important commodity, and if there is no indication that Europeans are individually less well-endowed with intellectual capacity than, say, Americans or Japanese, why, Danzin asks, should Europe take the risk of being outstripped by its rivals "in the only specialised field where it is not seriously handicapped—brainwork and inventive capacity"? And yet R&D expenditure per capita in Europe is less than half that in the US, with signs of the gap widening; whilst in Japan (where financial comparisons are inappropriate owing to much lower unit costs of Japanese research scientists) the number of specialists working in

R&D as a fraction of the total population is double the European figure.

The troubles are not all simply in money and numbers of researchers, however. Danzin is highly critical of the sort of structures that individual European nations have evolved in the academic, bureaucratic and industrial world and which they now carry over into the machinery of the EEC itself. Rigidity, resistance to innovation, personal immobility; these are the constraints which prevent Europe responding flexibly to a changing world, and which contrast so unfavourably with American experience. For the businessman and industrialist the attraction of Europe ought to be, but as yet is not, the possibility of selling in a market larger than any other in the world. For the scientist and technologist it is the diversity of Europe which ought to be attractive—the many different traditions each bringing different skills and approaches to bear on problems. But this diversity can only be harnessed if there is an easy flow of people and ideas around Europe. With the exception of certain large projects, this cannot be said to be happening at present—if anything Europeans pair off with Americans rather than with fellow Europeans. Language is, of course, a barrier, and there is no sign (in Britain at least) of any improvement on this score. But it is more than language; there is much insularity of attitudes.

Danzin does not propose a crusade for the Europeanisation of science—his final chapter is entitled "Proposals for Mild Treatment". He notes that the research budget of the Community is only around 1% of the total for individual nations, but believes community-wide research has made encouraging progress, despite "pointlessly cumbersome" decision-making circuits. He would like to see the European research budget grow to a "substantial" level with a new executive body of more flexibility, able to take quick decisions and fund on a multi-annual basis. The new body would have not just to incorporate the existing European laboratories but also to stimulate them to take part in a "vast system of extra-mural exchanges".

Some will be disappointed that after such an astute analysis of the European problem, and after such a ringing declaration of the importance of science and technology, Danzin does not come up with some highly radical solutions. But this is the work of a realist; developments have to be evolutionary, and they have still to meet the approval of nine selfish governments, so proposals for a bonanza will get nowhere. On the other hand, a revolutionary change of attitudes costs nothing and can be effected almost overnight. A careful reading and re-reading of Danzin's quiet book by all of those concerned about the future of the EEC and its institutions would undoubtedly change a lot of minds. □

Recombinant DNA research: private actions raise public eyebrows

Rival scientific groups, often working towards common goals, share a close network of financial supporters.

David Dickson reports

LAST Thursday, the US Court of Customs and Patent Appeals confirmed its earlier decision that patent applications could be granted on two separate microorganisms, the one developed by scientists with General Electric, the other by Upjohn Co.

For the second time in 18 months, the court reversed a decision by the Patents and Trademarks Office refusing the patent applications on the grounds that the microorganisms were products of nature. The re-evaluation was made necessary by a Supreme Court ruling last June that the Appeals Court should reconsider its verdict in the light of a decision that a particular computer program was not patentable.

Three of the five Appeals Court judges, in repeating their previous position, said that they failed to see any connection between the computer program and the microorganism cases. And it could therefore be some time before a final verdict—the outcome of which is being awaited before patent applications are considered for a growing list of recombinant DNA inventions—is reached, since the Patent Office may well choose to take the case back to the Supreme Court for final clarification.

Whatever the outcome, however, growing confidence in the US business community that the development of recombinant DNA technologies promises large profits has led to a steady flow of venture capital to support research. No one has yet made very much money, but high commercial expectations have helped raise the value (on paper) of the five small private companies most deeply involved to a figure estimated at more than \$150 million.

In the rush for commercial pay-offs, however, some of the tactics used are beginning to raise various concerns on Capitol Hill, such as whether private industry's voluntary compliance with the National Institutes of Health's guidelines provides an adequate basis for ensuring the same degree of safety in private industry as the guidelines currently require in university laboratories.

Some of the issues are:

- Private corporations have already financed research by US scientists in various European laboratories to carry out experiments for which the facilities required by the guidelines at the time were not available in the US.

- A major pharmaceutical company is providing backing for two of the leading three teams investigating the possible production of human insulin by bacteria (and has tried—unsuccessfully—to gain a license to develop the results of the third team).

- A transnational recombinant DNA company has been set up by a Canadian multinational company with a group of leading scientists from Europe and the US. Capital for the company has been raised on both sides of the Atlantic, and the arrangement permits experiments to be located in the country offering the most acceptable environment for the research.

- As reported in *Nature* last week, at least one US company is already planning to conduct experiments involving more than ten litres of culture without receiving prior formal approval from the NIH, as the current guidelines require of federally-sponsored research.

The rapid growth of the small research companies, representing a direct marriage between university research workers and finance raised on the venture capital market, bears many similarities to the growth of the electronics industry ten years ago. Although most of the large pharmaceutical companies are building up their in-house capability to do such research, in most cases they have been less aggressive and slower to accept the commercial potential of the new technology than outside investors who are more prepared to take speculative risks.

In addition, rather than selling the licence to develop patents arising from their research direct to the major

companies, a number of scientists have preferred to set up their own commercial ventures, often using the money they have raised to licence the patents from work they have carried out on federally funded grants. "A fact of life is that the vast majority of talent in the field is in the universities at the present time," says Professor David Jackson of the University of Michigan.

Five relatively small companies currently occupy the centre of the stage. These are:

- Cetus Corporation, set up in Berkeley, California in 1971 on an initial capital of \$5 million, and currently carrying out research on a contract basis for industry in a number of areas, including biomedical, chemical, food and agricultural technologies. Cetus has opened a P3 facility, and its current value on paper is estimated by president Dr Peter Farley as around \$65 million. Almost half of this stock is owned by Standard Oil and National Distillers Company.

- Genentech, Cetus' rival across the bay in San Francisco, which claims to be "the leading company in the application of recombinant DNA techniques to problems in human health care". Set up in 1976 by Robert Swanson and Dr Herbert Boyer, Genentech is also interested in a wide range of applications, but has gained most publicity for its work on somatostatin and insulin.

- Biogen, a company incorporated in Luxembourg, which was set up last year by Mr Dan Adams, then head of the venture capital division of International Nickel. Biogen has nine scientist co-founders from both sides of the Atlantic, and has so far concentrated mainly on working towards pharmaceutical products such as insulin, interferon and a possible hepatitis vaccine. Adams estimates the current value to be about \$50 million and Biogen is currently constructing laboratories in Switzerland to P3 containment levels.

- Genex, established in 1977 by Dr Jackson of Michigan and two others. It is concentrating on industrial processes involved in, for example, the food and chemical industries. Genex plans to open a laboratory in Rockville, Maryland in the near future, and to announce a major deal with "one of the fortune 500 companies", within the next four weeks according to president Dr Leslie Glick.

- Bethesda Research Laboratories, set up three years ago and already a major

supplier of restriction enzymes. It started moving into recombinant DNA research last summer, and has opened a P2 facility also in Rockville (rapidly becoming the "route 128" of molecular biology, largely because of its proximity to NIH).

In addition, collaborative research, in Waltham, Massachusetts, which already supplies materials such as synthetic genes required for research to a number of the companies listed above, is now contemplating entering the field directly, according to its president, Dr Orrie Friedman.

At the scientific level, research groups supported by the various companies are frequently exploring different paths towards the same goals, characterised by the fierce—though usually friendly—rivalry common to all fields of science. Some of these goals include the production by bacterial means of insulin, interferon, growth hormone, and various industrial enzymes.

At the financial level, however, the situation is slightly different. Apart from Bethesda Research Labs, which is financed by a private family trust, the other four companies share some common financial backers in what one participant acknowledges to be a "somewhat incestuous" relationship.

For example, Kleiner and Perkins, an established West coast venture capital firm which supplied the backing for electronics companies such as Fairchild Industries, has provided substantial support for both Cetus and Genentech, although Dr Farley of Cetus says that the standard oil support now puts the company apart from the other three. Similarly, New Jersey, which receives its own funds from companies such as Aetna Life Insurance, Emerson Electric, and the Monsanto Chemical Company, has a stake in Genentech, and last year provided a substantial amount of capital to Genex. Mr Gerald Large, president of Innovent, is now a director of Genex.

Perhaps the most extensive involvement has been that of International Nickel, (INCO), a Canadian based mineral company, which set up a venture capital division operating from New York in 1975 to support "worthwhile entrepreneurial investment opportunities in Canada, the US and Europe." Soon after it began operations, the then head of the division, Mr Dan Adams, selected recombinant DNA technology as a fruitful field for investment "I felt that this was the most exciting field of technology for investment for the immediate future," he said last week.

In line with this conviction, INCO bought a small amount of stock in Cetus in 1976 valued at about \$500,000

and subsequently in 1977 bought a larger, 10% share in Genentech. Then in 1978, with advice from Genentech—(which is now demanding a share in the equity in return), and a scientific board brought together by Dr Walter Philip Sharp of MIT, INCO set up a Gilbert of Harvard University and Dr new company, Biogen, with Adams as president (Adams has since left both INCO and Biogen, but is looking for new areas to start a similar venture).

INCO was incorporated in Luxembourg, "which has some attractive tax advantages", according to Adams, and sponsors research in the laboratories of a number of members of its scientific boards, such as that of Dr Charles Weissman, of the Institute for Molecular Biology at the University of Zurich.

Financing provided largely by INCO through Biogen has already allowed Gilbert to carry out experiments into the production of human insulin at the Microbiological Research Establishment at Porton Down in the UK, since at the time the P4 containment facilities required by the NIH guidelines were not available in the US.

Of the major pharmaceutical companies, Eli Lilly has been the most aggressive in pursuing potentially valuable research results (as well as the most vocal critic of attempts to legislate basic research in the private sector). The company currently controls 80% of the \$140 million domestic insulin market, and is keen to maintain this position.

Last Autumn, Eli Lilly entered an agreement with Genentech clinched soon after scientists in the latter company announced they had produced human insulin from bacteria (although the insulin produced in this way has yet to be shown to be biologically active) under which the two companies will carry out a joint long-term manufacturing and marketing programme.

In addition, Eli Lilly has entered a separate agreement with Dr Howard Goodman and Dr Bill Rutter of the University of San Francisco in the Department of Biochemistry and Biophysics. The pharmaceutical company has provided over \$250,000 to support the laboratory's research into the production of human insulin, money which last year allowed research workers from the laboratory to carry out experiments in France which could not be done in the US.

In return for providing financial support, the company expects first refusal on the license to develop any patentable results which arise from the research.

In addition to the above two agreements, Eli Lilly recently bid unsuccessfully to purchase from Harvard University the rights to develop the patent filed by Gilbert for research

developed in connection with other research teams at Harvard (the British drug company Boots, also expressed interest in licensing the patent but Harvard decided that the patent should go to Biogen).

Within this complex of financial and corporate interests, those involved are taking pains to emphasise that all research—at least that which is carried out in the US, and at least with respect to the technical aspects of containment levels—is conducted in accordance with the criteria in the NIH guidelines.

For research outside the US, however, it is generally accepted—even by NIH itself—that these guidelines need not apply, strictly but that the research should be done in compliance with local requirements (making countries with relatively low requirements attractive).

However, evidence that companies are already more than willing to move abroad to carry out research that cannot be done in the US is beginning to worry US lawmakers, which have so far held back from legislating over the private sector. "This is certainly something we are keeping a close eye on" a staff aide to Senator Adlai Stevenson's science subcommittee said last week.

In return, companies are worried about a proposal by the Food and Drug Administration to introduce regulations that would require all research leading to products for which licenses are applied to have been conducted under the NIH guidelines. They are suggesting that, if the work is carried out abroad, the compliance should be with local guidelines. "It would be silly for FDA or NIH to try to police the world" said Adams.

Meanwhile other critics of existing policy and of the NIH sponsored decision processes are concerned that without legislation explicitly covering the private sector, there will be no way of guaranteeing the safety of the procedures that this sector adopts. In the wake of last week's nuclear power incident at Harrisburg public credibility of claims of minimal danger is running low (already scientists at Tufts University have demonstrated that a "disabled" E. Coli strain classified as EK2 is capable of surviving up to 90 hours in the human gut, far longer than was initially anticipated).

"The question remains who is going to control both the process and the products of this research," says Dr Susan Wright of the University of Michigan. "Given that great uncertainties still exist, and the fact that risk assessment experiments have not yielded uniformly negative results and have indicated some areas for renewed concern, it is important that Congress does all that it can to guarantee the safety of those involved." □

COGENE plays up benefits, plays down risks

IN A surprise statement last Sunday, the foreign secretary of the Royal Society, Mr Michael Stoker, announced the lifting of the ban on reporting of what promises to be the most important meeting on the risks and benefits of recombinant DNA techniques since Asilomar, the conference held in California in 1975 during which scientists called for strict control of the use of recombinant DNA techniques.

COGENE, the Committee on Genetic Experimentation of the International Council of Scientific Unions (ICSU), had previously issued a directive that the whole proceedings at Wye College, Ashford, Kent, UK would be off the record. The directive was the result of what was felt to be unbalanced press coverage concerning recombinant DNA risks, particularly after Asilomar.

Dr Stoker, however, when opening the meeting, asked participants to

"tear up that note". There had, he said, been a change of attitude on the organising committee. But the note had already had its effect—only three journalists were present and they were from specialist scientific magazines, including *Nature*.

We are therefore now able to report that COGENE is shifting its attention from risks to benefits. Supported by UNESCO and the World Health Organisation, it is planning to hold a series of two to three week teaching courses in recombinant DNA techniques in developing countries beginning in January 1980. COGENE chairman Dr Bill Whelan said: "We have the money and we just want to find a country that would appreciate our help." Recombinant DNA techniques could be of great benefit in Third World countries, Whelan believes, particularly in agriculture, where they could help in a rapid assessment of the

molecular genetics of local crops.

Meanwhile, however, COGENE is slowing up its attempts to assess the risks of the technology. "We have run out of good ideas for risk assessment experiments", said Dr Anna-Marie Skalka, who chairs the COGENE subcommittee on risk assessment. However, Professor Mark Richmond, a member of the UK's Genetic Manipulation Advisory Group (GMAG) who will report on his own assessment experiments at the meeting, believes that the real problem is finding willing researchers to do the work. "I took it up to show willing", he said, but the work takes up time, lab space and people especially when there is a wide feeling in the scientific community that the risks are minimal. "If the UK Medical Research Council wants people to assess risks it may have to force them to do it", he said.

Robert Walgate

GMAG states the position on 'self-closing'

At the end of last week, GMAG issued a statement designed to satisfy the "urgent need to clarify certain issues" and to remove "any uncertainty of ambiguity about present requirements". As expected some self-cloning experiments—those using *Escherichia coli* K12 and other well-characterised non-pathogenic laboratory strains of *E. coli*, *Bacillus subtilis*, *Bacillus stearothermophilus* and *Saccharomyces cerevisiae*—are exempted from statutory notification.

In general, however, self-cloning experiments are still considered to be within GMAG's remit. "The group is satisfied" says the statement "that many self-cloning experiments are without conceivable hazard", but it "interprets the definition of genetic manipulation to cover self-cloning experiments". It also acknowledges "that there has been uncertainty on this point and that some users have interpreted the definition to exclude such experiments". The definition of genetic manipulation used by GMAG is "the formation of new combinations of heritable material by the insertion of nucleic acid molecules produced, by whatever means outside the cell, into any virus, bacterial plasmid or other vector system so as to allow their incorporation into a host organism in which they do not naturally occur but in which they are capable of continued propagation".

In future, therefore, all self-cloning experiments with systems other than those specifically designated as exempt, should be notified to GMAG which "will advise on containment". Those working with exempt organisms are

asked to provide voluntarily "a limited amount of information about their plans to help (GMAG) keep in touch with all developments in the field". This should include "species and strains, the place of work and the scientists responsible".

GMAG is also seeking to amend regulations to cover the use of "products of genetic manipulation which are capable of self-propagation". Voluntary notification of the use of these products is requested so that GMAG can advise on containment. However, exemptions from this will include the products of those self-cloning experiments which are exempt and the insertion of *Xenopus* genes coding for 28S, 18S and 5S ribosomal RNAs into prokaryotic DNA. Users are invited to propose other products of recombinants which could be added to this list. Special consideration is also to be given to scaled up work involving the growth of self-propagating products in volumes of 10 litres or more. Arrangements for this type of work are still under discussion.

GMAG still feels unable, according to the statement, to accept some of the principles that the United States and other countries have adopted, following the NIH lead. Nevertheless it will study the NIH guidelines to see if there are some procedures which could be adopted in the UK in the hope that collaboration with other national authorities will bring about some uniformity of procedure.

GMAG's terms of reference are restated as advising all those concerned in any way with genetic manipulation,

continually assessing new genetic manipulation techniques (and new containment methods) and advising on appropriate action. It is also required to "maintain appropriate contacts with relevant government departments, the Health and Safety Executive and the Dangerous Pathogens Advisory Group", and to keep records of containment facilities and the qualifications of biological safety officers. □

UK minister criticises COGENE meeting

Mr David Ennals, UK Secretary of State for Health and Social Security, expressed his concern last week at the original intention to ban reporting of this week's COGENE meeting. "Basically, I'm opposed to secret conferences", he told the genetic engineering subcommittee of the House of Commons Select Committee on Science and Technology. "Far too much in the field of science is done behind closed doors".

The subcommittee was holding its first public session after a recent visit to the US. Mr Ted Leadbitter cited a recent US survey which had found that of 18 countries using recombinant DNA techniques, the US and the UK had the most stringent regulations. Might this encourage valuable work to go abroad, he asked? Mr Ennals said he thought the most important thing was to "watch the hazards carefully" if we did not want to upset the balance between risk and benefit. GMAG he thought was flexible enough to do this. □

European physicists discuss the "great projects"

A SELECT group of European physicists met in Rome last week to learn of Europe's plans for future "very large capital projects" in astrophysics, sub-nuclear physics, synchrotron radiation and nuclear fusion—projects which, the organisers say, could dominate research and development until the end of the century. They were there by invitation of the European Physical Society, whose president, Antonino Zichichi, had decided that the meeting was needed to inform key physicists with an interest in any one of the projects of the plans for the others. All the projects are likely to compete, at least to some extent, for future funds.

Professor L. Woltjer of the European Southern Observatory (ESO) headquarters in Geneva, told the meeting that after the present generation of ground-based single dish telescopes of diameter 3-6m, the future of Europe's optical astronomy will rest with the joint NASA/ESA Space Telescope, due for launch from the Space Shuttle in 1984, and a ground-based Very Large Telescope (VLT).

So far the latter is only an idea but it is being considered seriously by the ESO. The current plan is that it would have a diameter of about 16m, would probably be sited at the ESO's site in Chile and would become operational in 1990: its cost is estimated at about \$100 million. As it is unlikely that a single dish of 16m diameter could be built, the VLT would probably be a multi-mirror tele-

scope.

The Space Telescope and the VLT will be complementary, according to Professor Woltjer. The former will be used for gathering data on very faint sources which could never be observed by a ground-based telescope because of the masking effect of the Earth's atmosphere. However, because it is relatively small (2.4m diameter), the Space Telescope will be limited in the number of photons it can collect. The VLT with its large collecting area, will be capable of collecting many more photons and will therefore be suitable for detailed spectroscopic analysis of relatively bright sources.

In radio astronomy, Europe is already active in very long base interferometry (VLBI), the aim of which is to produce a two-dimensional map of radio sources. There are plans to extend the VLBI network by building more receivers and also by using one of the European Space Agency's future communications satellites as a reference point for phase and amplitude information. The French are looking at the possibility of using VLBI at optical wavelengths. A major problem however, is that the engineering tolerances of the receivers have to be very high because of the small wavelength.

Fusion scientists are also planning their next move. According to Professor Palumbo from Brussels, an international team met last January to start discussing the machine to follow the Joint European Torus (JET) which is

just getting underway at the Culham Laboratory in the UK. Just the week before the meeting, he said, the EEC had increased the budget for European fusion research by 20 million accounting units.

Two plans for major future particle accelerators were discussed. One is Europe's plan to build a large electron-positron storage ring (LEP) (see *Nature* 12 October 1978, page 469 and 14 December 1978, page 658), the other is the Soviet Union's plan to build a 3 TeV proton synchrotron. Work on the latter has been going on for "a long time" according to Professor Siderov of Novosibirsk who presented the project instead of Professor K. P. Myznikov of Moscow who did not attend the meeting. He could not say when the machine would be built or how much it would cost, but seemed confident that it would be built at some time. Professor M. Vivargent of CERN said that the design for LEP currently favoured would cost about SwFr 1000 million and should be built by 1988. More should be known at the end of this year, however, when the report of the latest study group would be ready.

Like LEP, the European Synchrotron Radiation Facility (ESRF), is also awaiting the publication of a report at the end of this year which should also lay down the type of machine the physicists would like. It will then be up to the politicians to decide whether or not that is economically feasible. **Judy Redfearn**

Harrisburg leak 'the worst accident in nuclear history'

THE type of human and mechanical failure which occurred in the nuclear power plant near Harrisburg, Pennsylvania last week and led to the discharge of a cloud of radioactive gas into the surrounding environment, has a 50:50 chance of happening in 400 reactor years, according to Dr Chauncey Starr, Vice-President of the US Electrical Power Research Institute. Speaking at a press conference earlier this week, Dr Starr said that "on the technical side this accident, while no-one wanted it, has a statistical probability that falls within the predicted probability of this type of incident. We have had 400 reactor years of operation of nuclear power and the earliest statistical analyses indicated that low level releases of radiation due to equipment failure would have this kind of statistical probability".

The accident resulted from an overheating of the core of the reactor causing some damage to the fuel rods. The emergency cooling system had flooded the core with water, but the contaminated water, some of which escaped through the roof of the plant as steam, was largely responsible for

the escape of fission products such as xenon, krypton and iodine into the local environment.

A critical problem still to be resolved is a 1,000 cubic ft hydrogen bubble trapped in the reactor core. Efforts to redissolve the bubble have failed and the radiation levels inside the plant are too high to release the pressure manually.

After a second release last Saturday a reading of 1,200 mrem per hour was taken at the gas vent, 25 mrem per hour south of the plant site and 15 mrem per hour within a five mile radius. Street and doorstep measurements in Harrisburg ranged from 2 to 5 mrem per hour. A normal chest X-ray produces 30 mrem of ionising radiation. Thus the inhabitants of Harrisburg, 10 miles from the plant are receiving the equivalent of from one to five chest X-rays per day with plant officials predicting several more days of radiation leaks. The possibility still remains that 600,000 people in a 20-mile radius around the plant may have to be evacuated. □

Finland turns to wood and peat for energy

ONE of the last acts of Finland's outgoing government was to accept, on 15 March, the report of a special commission on energy resources, which advocates 40% self-sufficiency by 1990. This programme, which will entail increased use of peat and wood, is effectively a reversal of a previous policy which envisaged a decrease of self-sufficiency from 29% in 1977 to 23% in 1990.

Since Finland's wood processing industry consumes approximately one quarter of all its energy and one third of its electricity, it would seem ecologically appropriate that it provide some of its energy needs. This it already does by providing some electricity generating plants (which in 1977 produced 7.5 TWh of electricity) with fuel in the form of wood wastes. Finland's Centrist Party, however, would like to go further than the commission's proposals and is suggesting an ultimate energy self-sufficiency of 50%. It says that proper use of wood wastes could replace up to 30% of Finland's oil imports. It is also advocating the growing of 'energy woods'—willow and other non-commercial timber. Finland's Forestry Research Institute is at present researching into this possibility, which would have the advantage of using otherwise unprofitable marginal and scrub lands. The main problem however is finance since planting and management of such 'energy woods' is highly labour intensive.

According to the 1977 forecasts, Finland's annual consumption of primary energy sources was expected to rise from 23.0 to 33.2 Mtoe by 1990—an increase of some 44%. Of these totals, oil consumption was expected to rise from 12.2 Mtoe in 1977 to 15.9 Mtoe by 1990. In 1977, approximately 70% of Finland's oil imports came from the Soviet Union, and it was hoped that the increase would also come from there.

Recently, however, the Soviet Union has been unable to meet Finland's increased demands, apparently due to similar increases from domestic and Comecon consumers, and difficulties in bringing the new Siberian fields on-stream. At the same time, OPEC prices have continued to rise, and the Soviet Union raised its prices proportionally—14% last December, and a further 8–9% last week.

Furthermore, Finland's two supertankers are not allowed to pass through the narrows between Denmark and Sweden if loaded to their full 100,000 tonne capacity. A major rethinking of energy policy seemed timely.

Making a grab for home-grown timber

Being a relatively flat country, Finland has only a limited number of sites suitable for hydroelectric plants, and these are already exploited virtually to full capacity (12.1 TWh in 1977). Nuclear power at present provides some 7% of all generating capacity from the first set at the Loviisa power station. A second set is under construction at Loviisa and two sets at Okiluto. The possibility of a third nuclear power station with a total capacity of 1 GW is still under discussion, but no decision is expected until the early 1980s.

Finland, incidentally, does not seem to have a vocal anti-nuclear lobby. However, on accepting the Soviet tender for the Loviisa plant, the Finns demanded far more stringent safety precautions than were then normal for Soviet reactors, including containment buildings (seen by the Soviet designers as a capitalist trick for inflating construction costs), redundant cooling systems and improved computerised controls. When the Soviet Union was unable to supply these additions, the Finns went shopping in Holland, West Germany and the USA.

Nuclear power, however, depends on foreign suppliers, not only for the construction of the station (the Soviet Union for Loviisa and Sweden for Okiluto) but also for nuclear fuel. If Finland is to become relatively more self-sufficient, wood and peat will become considerably more important.

Until very recently, peat which at present accounts for only 1% of Finland's energy production, had not been considered a commercially viable alternative. Earlier this month, however, the then Minister of Trade and Industry, E. Rantala announced a new agreement between Neste Oy, the Imatra Power company and the Navire Company on the study and adoption of wet carbonisation. This process removes most of the water from the peat, giving a fuel that is comparable with coal and contains only some 10% of water. Liquefaction of peat, said Mr Rantala, is also to be studied and the next supplementary budget is expected to allot additional funds for peat research.

Vera Rich

Hungary's careful use of pesticides for plant protection

"CHEMICAL pesticides, even if used extensively, never harm the wild life economy, provided that they are applied professionally." So said Mr Ferens Hargetai, head of the plant protection department of the Hungarian Ministry of Agriculture, at a seminar in Cambridge, England last week.

Hargetai's statement might well alarm some ecologists, particularly when joined to his definition of environmental protection. By this, he said, "we mean, whether confessed or not, the human being rather than the environment itself. Speaking about environment protection, one never thinks of the protection of the Colorado beetle or house fly, though these also belong to the environment in the same way as the singing birds or the national parks do".

However Dr Illes Desi, of the National Institute of Hygiene, suggested at the seminar, that developing an appropriate pesticide strategy was by no means simple. "More pesticides", he told *Nature*, "mean more food—but also more pollution."

The Cambridge seminar was part of the UK-Hungary trade and technology cooperation programme, and it was the Hungarians who asked specifically for a meeting on pesticides. Hungary has an excellent record of awareness of pesticide hazard. Mr Hargetai said it was the first country in the world to ban DDT, aldrin, dieldrin and HCH. "We found that the concentration of DDT in the population was very high—12 to 16 ppm. This was among the highest in the world. So it had to be stopped".

In the same year (1968), a set of requirements for the registration of pesticides was drawn up. In 1972, a new system was introduced classifying pesticides from the point of view of environmental hazard. This meant certain pesticides could not be used within a given distance of a river; some may only be applied by trained experts.

These experts play an important role in Hungarian agricultural planning. By law, every state farm must have on its staff a "plant protection engineer". Cooperatives and the few remaining private farms can (and in the case of dangerous pesticides, must) hire the relevant experts from the government-sponsored Plant Protection Service.

This service is concerned with the whole range of plant management problems including research into crop pests and diseases. In 1975 a forecasting system began which has reduced considerably the amount of pesticide needed. □

Breakthrough by PLUTO: The PLUTO collaboration, working on the e^+e^- storage ring at DESY in Hamburg, announced last week the discovery of new evidence to lend support to Quantum Chromodynamics (QCD) as the proper theory for strongly interacting particles. Recent data at DESY shows evidence for a three-jet structure in the decay of the u -quark just as predicted by some QCD models. QCD model calculations for e^+e^- collisions show that the u -quark decays into 3 gluons which give rise to 3 jets of high momentum particles. The identification of such multi-jet events is very difficult because of severe backgrounds from other processes. The PLUTO analysis is based on a sample of over 2,000 events collected in the u -quark resonance region. Earlier studies of such jet structures have been inconclusive. Only after many refinements of its data analysis procedures has the group been able to confirm the existence of 3-gluon jets.

Boost for biotechnology: A UK working party on biotechnology is being set up to review developments in this rapidly expanding field and to recommend actions which will help British industry. The sponsors of the working party are the Advisory Council for Applied Research, the Advisory Board for the Research Councils and the Royal Society. The chairman will be Dr A. Spinks of ICI. The group is likely to take a very wide look at the subject in disciplines such as photosynthesis, recombinant DNA, fermentation biomass, cell fusion and so on; applications are likely to range through pharmaceuticals, waste disposal, food technology, metal mining, oil production and many others.

Health check on UK radiation workers: The Medical Research Council (MRC) is to conduct epidemiological studies for the UK Atomic Energy Authority (UKAEA) to investigate the effects of long term exposure to low levels of radiation on UKAEA workers. The research team will probably survey the health records of all present and past UKAEA workers and visit all its institutions. Workers employed by British Nuclear Fuels Limited (BNFL) will not be included in the survey as BNFL are carrying out an independent survey. According to Dr Tony Vickers of MRC Headquarters, the head of the study has still to be appointed and results will not be published for at least three years. The whole survey will be monitored by a steering sub-committee of MRC's Protection against Ionising Radiation Committee, chaired by Dr R. H. Mole, a former director of Harwell's Radiobiology unit.

FOE requests reactor safety information: In the wake of the Harrisburg accident (see page 497) Friends of the Earth has renewed its request to the UK Secretary of State for Energy, Tony Benn, to publish the Health and Safety Executive's full report on pressurised water reactor safety. Citing the recent disclosure of the Union of Concerned Scientists "nugget file" of "astonishing" safety deficiencies at US power stations, the closure of five power stations due to a factor of six deficiency in the design of safety piping and the continuing Harrisburg events, FOE criticises the HSE for refusing to release detailed safety studies of PWRs or of the British Gas Cooled Reactor (AGR). In addition, FOE requests Benn to submit the full reports to "a proper review process" by independent analysts.

Meanwhile, British Nuclear Fuels has announced that the latest Windscale leak (29 March) has been located in an out-of-use building that had been used to store highly active wastes before their transfer to buffer storage tanks. BNFL is now investigating the route by which the leak

reached the borehole and is satisfied that "there is no hazard to workers on the site or to people in the nearby community". The radioactivity measured in the borehole was 0.1 curie per litre. It was not possible to obtain the energy of the radiation for conversion to dosage (rems).

US urged to centralise assessment of cancer risks: A single scientific organisation responsible for identifying and characterising potential carcinogens across a range of government agencies has been recommended in a report prepared by the staff of the US Office of Science and Technology Policy. Such an organisation, which it is suggested should be based on an expansion of the National Toxicology Programme established last year by the Department of Health, Education and Welfare, would have two main responsibilities: to identify those substances which pose a potential carcinogenic risk to humans, and to characterise in quantitative terms the nature of the risk and the degree of certainty of current estimates.

Priority for scientific analysis should be given to chemicals for which cost-benefit analysis performed with existing data suggests that regulation be indicated, but leaves too much uncertainty to justify immediate action. "Priority setting and coordination of testing ideally should be done by a single group with input from all relevant agencies" says the report.

Environmentalists criticise secrecy of recombinant DNA meeting: Three US environmental groups have issued a statement criticising this week's meeting on recombinant DNA research organised by the Royal Society and COGENE for placing a cloak of secrecy around its deliberations. The meeting, participants of which had been told that they should not report directly on the proceedings, has been discussing the development of guidelines by different countries to regulate this research. Leslie Dach, of the Environmental Defense Fund, said that "it is a disservice to the discipline of science that the press and the public be excluded from a meeting that is concerned with a new technology of potential global impact." (The ban on reporting was suddenly lifted at the start of the meeting, see page 496).

EDF, Friends of the Earth and the Coalition for Responsible Genetic Research have claimed that the \$200 attendance fee is a barrier to the public against attending the conference. "An international group such as UNESCO cannot afford to condone exclusion of the news media and other observers from an issue as important and debatable as genetic engineering," said Lorna Salzman of Friends of the Earth (COGENE is organised under the auspices of the International Council of Scientific Unions, which is supported by UNESCO).

US study claims benefits of reducing air pollution outweigh costs: The US Environmental Protection Agency has issued a report saying that the costs of cleaning up air pollution from factory chimneys is considerably less than the economic benefits including the reduction in health expenses. According to the EPA, the annual health spending of the US would be reduced by \$40,000 million if pollution from factories was reduced by 60%, although this figure has already been queried by the business community. The report was prepared by research workers at the University of Wyoming, the University of New Mexico and the University of Southern California. It stated that a 30% improvement in the air quality of the Los Angeles region would produce an annual benefit of \$500 per household by raising real estate values.

Swiss go to polls again on nuclear issue

Local democracy continues to block nuclear power in Switzerland. Geoff Milnes explains the latest debate over waste disposal.

THE further development of nuclear power in Switzerland is grinding to a halt because of the refusal of local authorities to allow test borings in the search for suitable repository sites for radioactive waste. This is for many people an unwelcome effect of direct democracy and local autonomy—two characteristics of political life in Switzerland of which the country is justly proud. Local resistance to test borings has led to a polarisation which has spread to the whole question of the role of nuclear energy. This became clear in the campaign leading up to the plebiscite on 18 February, in which 49% of the voters were in favour of a ruling which would probably have brought nuclear development to a complete halt, by demanding popular control of the siting of nuclear facilities by the local population surrounding the proposed sites.

Moreover the situation will remain critical if a revision of the law which recently passed through parliament is turned down in the next referendum, in May.

The present law governing nuclear power plants was put into force in 1959 with the idea of encouraging the peaceful use of atomic energy by the electricity companies, which are mixed

private and cantonal bodies run on a private enterprise basis. Licensing was placed in the hands of the *Bundesrat* (the seven-man cabinet) with no direct democratic or parliamentary control. There was little controversy until mid-1974 when newspapers reported surreptitious drilling by a little-known organisation, NAGRA, looking for repository sites for radioactive waste in a number of localities—without the permission of the local authorities.

This action, together with the obvious and painful dependence of Switzerland on foreign energy supplies emphasised by the oil crisis of 1973/74, a series of frightening projections of future energy requirements, and plans for building 10-15 nuclear power stations which appeared at about the same time, resulted in a tremendous upsurge of public interest and concern.

NAGRA (Nationale Genossenschaft für die Lagerung Radioaktiver Abfälle) is a cooperative organisation founded in 1972 by the "waste producers"—the companies operating or planning to operate nuclear power stations (six companies in all) and the confederal government (responsible for radioactive wastes derived from hospitals, industry and research)—each with one delegate on the administrative board.

This board contracts research in various directions, financed in proportion by the companies and the government—in waste treatment and conditioning, in the development of repository concepts, and in geological studies. The latter has turned out to be the politically critical area.

Switzerland is one of the few countries without a geological survey—and there is no tradition of free flow of geological data, since most studies are carried out by private companies in competition with each other. The NAGRA research was thus contracted out to a private geological bureau. Also, NAGRA became a member of a further institution, KUS (Konsortium für Untertagsspeicher), set up to coordinate all work on underground storage, including the storage of oil and natural gas. In 1974, none of these bodies were in the public eye and the complicated inter-relationships made it difficult for the individual landowners to grasp for what and for whom the geological investigations, including test drilling, were to be carried out, when permission was being sought for land access.

Whether this confusion was a result of a basically nuclear legal situation (NAGRA's view) or whether it was the result of a deliberate policy of secrecy and stealth (the anti-nuclear front's opinion) is hard to judge.

What the geologists say about where to bury the waste

A RECENT book* assesses the alternatives for disposing of the radioactive waste from Switzerland's nuclear power plants, assuming that by the year 2000 a final capacity of $5 \times 1,000$ MWe will be reached. From the geological point of view, radioactive wastes can be put into two categories, according to the length of time that isolation from the biosphere is required.

The first category, low-active waste (NAA), consists of contaminated materials from the normal running of power stations (filter residues, worn-out parts, tools, clothing, etc) and the radioactive debris produced on demolition after the projected 40-year running life. This material contains only short-lived radio-nuclides in small amounts and needs isolation for a few hundred years. The total volume will probably be about $85,000 \text{ m}^3$.

The second category is the high-level α -bearing waste (HAA) which originates from the reprocessing of

the spent fuel. Switzerland depends on foreign plants for fuel reprocessing, but must assume that high-level wastes from these plants will be returned to the country for disposal after an initial storage period. With present reprocessing procedures, which seem unlikely to change drastically in the near future, HAA will contain quantities of plutonium and α -emitters with long half lives which require containment times of at least 100,000 years. However, the total amount of HAA will probably be small (about 400 m^3).

However, several factors make Switzerland far from ideal for the location of radioactive waste repositories, particularly for HAA. These include the complicated geological structure, the humid climate and the complex hydrogeological conditions, the possibility of renewed extensive glaciation and the continuing tectono-seismic activity.

Near-surface mined cavities for low level waste: NAGRA has been contracting research in this direction for a number of years. Research has concentrated on anhydrite as the host rock for NAA repositories. Pure

anhydrite is suitable for cavern construction and has good sorption characteristics and thermal conductivity. It is also generally impermeable to ground-water near the surface, because of a "self-healing" effect caused by its rapid conversion to gypsum (with a volume increase of 60%) when water percolates along cracks and fractures. Anhydrite-bearing formations are widespread in Switzerland, though occurrences of pure anhydrite of sufficient size have not yet been found. The anhydrite occurrences known are all very impure and heterogeneous, often chaotically mixed with other rocks or found along fracture zones with rapidly varying thickness. Investigation on other potential host formations (shale, granite) have not yet been carried out. So, although a reasonable solution can be expected in this direction, the research and development programme is still in its infancy.

Deep borehole repositories for high level waste: The book proposes a fanned array of deep boreholes, penetrating a 350 m thick host formation at a depth of 1-2½ km. Various potential host rocks—rock salt, anhy-

Nevertheless, when the news broke that test borings in connection with the search for suitable underground repositories for nuclear wastes were in progress in several places without official knowledge or consent of the Gemeinde in question, a great cry went up.

Since 1974, no further test borings have been possible and the resolution of this stalemate has become a key issue in the nuclear power controversy. The core of the legal problem seems to be that the *Bundesrat*, under the law of 1959 which is still in force, is only responsible for site licences and permits once a site has been selected. NAGRA has always emphasised, however, that the test borings were exploratory, preceding site selection.

The *Bundesrat* has thus decided that they are governed by the normal laws applied to mining, search for oil, etc. for which the Canton is responsible, after consultation with the Gemeinde concerned. NAGRA lawyers maintain that the preliminary investigations must be considered as an integral part of the nuclear facilities themselves, coming under confederal law, and so the NAGRA put in applications for permits to carry out the borings to the Confederation Energy Office in 1976. These are still pending.

This is not the only legal bone of contention. The other important one concerns the licensing of the power stations themselves. The anti-nuclear

movement, supported by eminent lawyers, maintains that the proof of safety of nuclear power stations, a necessary condition for the granting of construction licences, includes also the safe disposal of the radioactive wastes, and that this cannot be produced prior to repository site selection, i.e. before test borings have been made.

This is just one of a series of irregularities which lead them to the conclusion that the nuclear plants now in operation (three, with a total capacity of 1,000 MWe) and the two 1000 MWe units at present under construction were illegally licensed. In the general atmosphere of public discontent, as illustrated by last month's vote, the *Bundesrat* has considered it politically inopportune to license further works under the old law (the Kaiseraugst works, whose site was occupied by demonstrators for 6 weeks in spring 1975, is one whose licence is still pending). Instead, it set a commission to work to revise it.

The new law, which passed through parliament in a number of turbulent sessions in spring 1978, contained several improvements and clarifications most of which intended to place the nuclear industry under stricter and more democratic control, with regulations which, in contrast to the old law, should rather discourage nuclear power growth unless absolutely necessary.

For the "borehole stalemate", however, the new law brings some relief—

test borings for power stations or waste repositories can be forced through by the confederal authorities by expropriation of land, if necessary. But the situation is still tense.

A section of the anti-nuclear movement decided that the stalemate suited their purposes well and have forced a referendum against the revision of the 1959 law (voting takes place on 20 May). In this, they have laid themselves open to accusations of illogical obstructionism by the nuclear power supporters—it is pointed out that one of the opponents' main arguments against nuclear power is that the problem of radioactive waste disposal is not solved, and yet their activities are directed towards preventing the very investigations necessary to reach a solution.

The anti-nuclear group is intent on preventing the waste disposal problem—which must be solved whether more nuclear plants are put into operation or not—from being approached in the scientific way it deserves. In so doing, it risks alienating that part of the anti-nuclear movement which takes a broader view of the whole energy problem and which is interested only in nuclear power being kept within carefully and democratically controlled limits. Be that as it may, the Swiss voters will be asked to decide another nuclear issue in May and an important public debate continues. □

Geoff Milnes is at the Geology Institute, ETH, Zurich.

drite, shale, marl, gneiss, granite—are possible, but few are thought to occur at convenient depths in sufficient thickness (probably only gneiss and granite). Potential sites are more likely to be found outside the mountain areas, i.e. under the Swiss Plain (Molasse basin). In the Alps, the deep structure is very complicated and difficult to predict and the danger of a new Ice Age and rapid glacial erosion in the next 100,000 years cannot be ignored.

A repository at 1–2½ km depth in a suitable area is unlikely to be affected by "external" effects—human influences, meteorite impact, volcanic eruption, glacial erosion—during that period. The relatively high seismic risk in some areas is a more serious problem because the fracturing associated with earthquake activity could affect the underground water circulation, which is critical for the integrity of any repository. Information about the numerous hot spring and mineral water occurrences indicate high permeabilities and rapid groundwater circulation in some deep formations. It will be necessary to gather detailed information on the flow types, velocities and chemistry of the

groundwater and on the sorption properties of the surrounding rocks in the vicinity of the repositories. These are local parameters, not predictable from surface studies—their investigation requires exploratory deep drilling and long-term, on-site experiments. This is a costly and time-consuming business and is by no means sure of success. Ten to 15 years of directed research will be required before the feasibility of this concept can be settled.

The alternative to the two concepts summarised above is cooperation in an international programme such as the "seabed" programme. Whether the two concepts can be realised also depends also on social and political aspects. The situation is aggravated by the lack of an established geological survey and because the research, being carried out mainly with private financial support in a piecemeal fashion, is not published and not made available to the general public. It seems clear, however, that even with the most favourable political developments, the scientific and technical problems are such that a practical solution and definitive site selection can hardly be expected

The Alps: their complicated structure may make them unsafe for long-term storage.

within the next decade, particularly for the HAA category.

Energy unit for global use

SIR,—Very large powers of 10 occur in discussions of global energy, one example being the exajoule (10^{18} joule). As this number is larger than the number of seconds since the big bang ($\sim 5 \times 10^{17}$) its size is difficult to appreciate, and a more intuitive unit is desirable.

Annual energy consumption is dimensionally power, and a good unit of power is a 60W continuously burning light bulb. (One could make it a 100W bulb, but that is slightly less modest.)

Furthermore it makes sense to report power per capita of the world population. Table 1 then expresses some important energy flows: the figures for 2000 AD and 2020 AD are based on exhibit 19 of Bloodworth, I. J. *et al.*, World Energy Demand to 2020, Executive Summary (World Energy Conference, London, 1977).

The table shows the low average efficiency of photosynthesis: there is evidently scope for the development of high energy yielding crops.

To see the proposed unit in action, we ask to what extent the deserts of the world—a somewhat fuzzy concept—could supply world energy requirements by direct conversion of solar radiation (to electricity, say). This is not a practical idea at present, but it is nonetheless important to have answers to such a question.

Assuming rather poor devices of 1% efficiency and an insolation at one tenth of the solar constant, one finds that the deserts would give an adequate yield for some decades to come (Table 2). Although there is in fact a great deal in hand at present, this advantage is being eroded.

The numbers for the energy consumption are reasonably small when expressed in these units and it is hoped that they carry an intuitive meaning.

Yours faithfully,

P. T. LANDSBERG

Military structure is off-target for science jobs

SIR,—David Horrobin's military solution to the problems of job opportunities and job security (8 March, page 118) could more aptly be described as the final solution, for if implemented, his ideas would further encourage short-term grant funded work using basic scientists as technicians and assistants. The lack of prospects offered would simply discourage those wishing to enter research as a profession and would commit research to a supportive role in advancing the careers of teachers and, in medical research, clinicians. But what is the problem he is trying to solve? If it is the "unequivocal... decline in research productivity between the years of 35 and 45" then his efforts are misguided: I challenge the myth that research scientists are more susceptible to 'burning out' than any other professional group. The "decline in research productivity" reflects a combination of withdrawal of short-term funding support (experience comes expensive) and the scientist's disillusionment with the abysmal career prospects.

In his proposed career structure we would know by the age of 35-40 whether or not we were suitable. If not, the alternative would be "the comfortable knowledge that they would have three years... to plan a second career." Who on earth is going to employ a middle-aged scientist stigmatised by his so-called "decline in research productivity." Like the universities, industry and government recruit largely at the graduate level and so even if they wished to pick up the academic 'casualties' they would not be able to do so. These proposals would also curb any independent thought, for the research worker would be continuously trying to please and impress the departmental 'Field Marshal' in the hope of being awarded another five years in

the despatches for efforts above and beyond the call of duty. Lastly, he resorts to the expedient of the gratuity payment. These always seem very generous at the time but, as many workers have recently found, the money is very soon spent, leaving the dole queue and senescence as the only feature on a bleak horizon.

Certainly scientists need a stimulus to work. But this should take the form of improved career prospects with adequate peer review by which effort, achievement and responsibility are rewarded; the game of Russian roulette in which the trigger is pulled every five years is no basis for a profession.

Yours faithfully,

MICK KADLUBOWSKI

Sergei Kovalev: remember a colleague

SIR,—Soviet biologist Sergei Kovalev is now in the fourth year of a seven-year term in a strict regime labour camp. He was sentenced in December 1975 for making known various violations of human rights by the Soviet state. Past support by scientists around the world has helped him to receive needed medical assistance and has ameliorated the harsh punishment given to him in the labour camp. Renewed efforts are now required to support him, lest he fade from the public eye and be left to the "mercy" of his jailers.

Scientists at the State University College at Buffalo and State University of New York at Buffalo have contributed funds and have purchased a journal subscription in Kovalev's name. It is sent regularly to him at his prison address. Colleagues at other institutions might well do likewise. Letters to Soviet authorities may also be helpful.

As spring approaches most of us in the northern hemisphere are going about our research and teaching and sharing the love of our families. Let us remind ourselves of our colleague, Sergei Kovalev, who is freezing in a Siberian labour camp because he dared to speak out in favour of human rights. We owe him a great debt and should do all that we can to help him in his time of need. As a symbol of our concern I suggest that each of us send a letter or greeting card to Dr Kovalev at:

Pochtovy Yashchik
No 5110-1BC
Moskva
USSR

This will let him know that he is not forgotten and will remind Soviet authorities that we have not forgotten our colleague. A blizzard of greeting cards would be an appropriate message at the end of this winter season.

Yours faithfully,

JAMES R. SPOTILA

Department of Biology,
State University College,
Buffalo, NY, USA.

Testing solar cells in space

from Andrew Holmes-Siedle

THE silicon photovoltaic cell was, as the Americans say, one of the first 'spin-offs from the space program'. There are now intensive development projects world-wide with the object of developing economical terrestrial photovoltaic power plants. At the same time, US scientists are still attempting to develop cells to give even higher efficiency in space. The problems faced in the latter work are worth mention for three reasons. First, the increased understanding of cell action, engendered by this work, will benefit all solar-cell designers; second, the problems faced represent interesting examples of the sophisticated engineering of semiconductor materials; third, some recent measurements of silicon cells, mounted on unmanned vehicles in space and monitored remotely, have yielded unexpectedly useful information in a different field, namely data on the characteristics of the near-earth radiation environment.

A paper by Richard Statler and Delores Walker of the US Naval Research Laboratories (in the *Proceedings of the International Energy Conversion Engineering Conference*, San Diego, August 1978) describes the design, exposure in orbit and interim

results of a solar-cell experiment in orbit at an altitude of 22,000 km. The satellite was the second Navigational Technology Satellite, NTS-2. This unmanned satellite is intended as a test-bed for new technology. It was launched on 23 June, 1977 and will be monitored for at least 3 years. The small array of cells, flown as an experiment, was independent of a large array of conventional cells which powered the vehicle. Various new types of cell were mounted in groups on the surface of the satellite and various thin, transparent cover glasses were applied in order to absorb the worst of the particle radiation. However, many energetic particles cannot be fully stopped. These penetrating particles degrade the performance of the cells. Significant information concerning the numbers of particles can be obtained from this degradation, as will be described later.

New techniques for increasing cell efficiency were being tested on this flight. For example, the texturing of the front surface of the silicon wafer allows more sunlight to be captured, the product is called a 'non-reflective' cell; very shallow n-on-p junctions give improved response to short-wavelength

sunlight and the product is called the 'violet' cell; the rear surface of the cell can be treated to repel current carriers and the product is called the 'back field' cell, the back surface of the cell can be polished to reflect penetrating infrared light back into the conversion region, the product is called the 'back reflector' cell; finally, solid-state processing of the silicon itself can improve the diffusion of current by removing any existing defects or by preventing the formation of point defects ('radiation damage') by particle radiation. The 'lithium-doped p/n' cell is an example of a radical modification of processing which has the sole object of reducing the sensitivity of the cell to radiation damage.

Four different manufacturers supplied a variety of developmental designs using the above techniques. The table lists the types of silicon cell flown, their photovoltaic properties and their degradation after 223 days in space.

At the top of this table come advanced designs from each of the major manufacturers of cells intended for use in space, showing that several alternative high-efficiency designs can survive well in space. The Solarex cells had excellent initial efficiency but suffered incidental electrode problems, so that no verdict can be passed on these. The only major difference between cells 6 and 9 was the technology for sticking on the cover glass for space solar arrays. This difference is far from trivial, since ultraviolet light from the Sun can seriously affect the adhesive. The use of a fluorocarbon polymer adhesive (on cell 6 only) gave rise to the lowest percentage degradation of any cell and this finding may represent a major step forward in space technology. If we wish to use the usual silicone adhesive, we are forced into the extra expense of depositing an ultraviolet-rejecting film on the cover-slide (compare cells 1 and 7). Cell 10, despite its low position on the absolute scale, represents a modest success for the older p-on-n junction technology. The structure is intrinsically more sensitive to radiation but the results

Table 1 Maximum power output of silicon solar cells after 223 days in orbit on NTS-2 (n-on-p junctions of area 4 cm² unless otherwise stated)

	$P_{\text{max}}(t)$ (mW)	% Power lost in 223 days	Manufacturer	Type

12.	33.3	46.5	Solarex	Vertical junction

demonstrate in space the laboratory finding that lithium atoms incorporated in the lattice can migrate and inactivate the defects created by particle radiation (Faith *IEEE Trans. Nucl. Sci.* NS-12(6) 371; 1972). Without the presence of lithium, another 12% of degradation would have been experienced. As regards silicon cell technology in general, one can say that the table shows that, given the economic incentive, silicon technology can be made to give still further advances in performance. A cell made from AlGaAs also did well in this experiment.

The NTS-2 experiment gave some useful information concerning radiation fluxes in space. The environment of the Van Allen belt has been crudely characterised but controversy continues about the absolute values of particle fluxes in orbits such as those of NTS-2 (a circular orbit of altitude 20,190 km, with the plane inclined 63.5 degrees to the plane of the equator) and of geostationary communication satellites (circular, 35,863 km, inclination 0). The main problem lies in measuring the spectra and spatial spread of the high-energy electrons which are known to circulate in geomagnetic trapping regions between altitudes 500 and 40,000 km. It is also difficult to follow the fluctuations of these values with time over several years. At the same time, engineers designing spacecraft are urgently in need of more precise predictions as to how rapidly their devices will degrade in this hostile environment. Thus any information which we can glean from well-calibrated cells such as those on NTS-2 is very welcome, especially since, on this flight, two experimental, remote-reading radiation dosimeters were also flown (Evans *et al* *IEEE Trans. Nucl. Sci.* 25, 1619; 1978). Certain p-n diode structures degrade smoothly and predictably under irradiation. High-energy particles produce recombination centres in the silicon by atomic displacement and these centres cause a reduction in minority-carrier diffusion length, L . Photovoltaic efficiency is proportional to L^2 . Thus, some solar cells constitute good, if limited, integrating radiation detectors. Results such as those tabulated here can be used to reduce the uncertainty inherent in the current models of particle fluxes in the Van Allen Belt and predictions of the effects of these fluxes on other electronic devices. The NTS-2 experiment has helped to increase our confidence in the fluxes of electrons to be encountered in this orbit (an annual damage-equivalent flux of 2×10^{14} 1-MeV electrons cm^{-2} per year). This figure is six times higher than some of the estimates used previously, which were based on the crude belt models already mentioned.

The NTS experiments, though modest, demonstrate that it is advisable to test theoretical predictions of performance in space by flying a 'test-bed' vehicle. The experiments also show that useful information can be obtained by employing, as detectors,

certain semiconductor device structures which are not yet widely used in radiation physics. □

Have quarks been found?

from P. I. P. Kalmus

MORE evidence for the existence of fractional electric charge has been claimed in a recent paper by G. S. LaRue, W. M. Fairbank and J. D. Phillips of Stanford University (*Phys. Rev. Lett.* 42, 142; 1979). Results from an improved version of their superconducting magnetic levitation experiment, indicate residual charges of $+\frac{1}{3}e$ on two small niobium spheres. These together with results presented two years ago by LaRue, Fairbank and A. F. Hebard (*Phys. Rev. Lett.* 38, 1011; 1977), if accepted at face value, show a total of four fractional charges in a sample of 7×10^{-7} kg of niobium. If these results are verified they represent a major discovery in physics, the detection of free quarks.

In classic experiments starting in 1910, R. A. Millikan sprayed microscopic oil droplets into an air gap between two parallel horizontal plates. The drops were charged by friction or by X-ray ionisation. They normally fell under the influence of gravity, but their motion could be changed and even reversed by the application of an electric potential difference across the plates. The viscous drag of the air caused drops to acquire terminal velocities which were functions of their electric charge. Individual drops were observed for long periods and their velocities determined. From many such observations Millikan showed that electric charge appeared only in integer multiples of a fundamental unit, e , whose modern value is approximately 1.602×10^{-19} coulomb.

Every elementary particle discovered so far has a definite charge ne where n is an integer, usually +1, 0 or -1. Many particles have been discovered in the past 25 years, most of them belonging to the class known as hadrons which experience the strong nuclear force. The study of hadrons revealed an order and symmetry which was interpreted by M. Gell-Mann and by G. Zweig as being caused by a substructure of constituents, named

quarks, having fractional charges of values $-\frac{1}{3}e$ and $+\frac{2}{3}e$. Antiquarks would have opposite-sign charges to these. Various quark models, including some which do not involve fractional charge, have had considerable success in explaining features of high energy physics, and the quark hypothesis is generally accepted today. Many searches for free quarks have been performed, but apart from an occasional false alarm have all proved negative. Indeed there are theories in which interquark forces increase with distance and quarks therefore are necessarily confined within hadrons. A comprehensive review of the search for quarks was written in 1977 by L. W. Jones (*Rev. Mod. Phys.* 49, 717; 1977).

Millikan's droplets had masses of around 10^{-14} kg and the absence of fractional charge on around 100 droplets gives an upper limit of about 10^{-13} for the number of free quarks per nucleon. It is possible to obtain a significant improvement in sensitivity by using much more massive objects, but then a stronger force is needed to balance them against gravity, and magnetic levitation can be used. In 1977, Fairbank and his colleagues published results from experiments which made use of the magnetic repulsion experienced by spheres of superconducting material. In a cryogenic apparatus, niobium spheres of mass 9×10^{-8} kg were levitated in a shaped magnetic field in which they had a natural vertical oscillation period of 0.8 Hz. An alternative vertical electric field of the same frequency was applied. The amplitudes of oscillations were measured and from these the net charges on the spheres were determined. The charge could be changed by $\pm e$ by bombarding the sphere with positrons or electrons from radioactive sources, so that as in the Millikan experiment, a series of charge values, differing by unit steps was obtained for each sphere. The experiment was performed with eight spheres, six of which showed zero residual charge. However sphere No 6 gave a residual charge of $+\frac{1}{3}e$ (to an accuracy of a few percent) on the two

P. I. P. Kalmus is Professor of Nuclear Physics at Queen Mary College, London.

occasions on which it was measured. Sphere No 3 gave a residual charge of $-1/2e$ on its first measurement, but after removal from the apparatus, cleaning in organic solvents and reinsertion gave zero charge. The authors went to considerable effort to understand and eliminate possible spurious effects which could mimic fractional charges. The main background forces are caused by induced and permanent electric dipole moments and by trapped magnetic flux in the spheres. All were claimed to be too small to account for the results. The samples were all accurately spherical and had been prepared carefully before use. To improve their oscillations the spheres had been heated to high temperature before being used. Five were heated on a niobium sheet and three on tungsten. Both fractional charges were found on the latter spheres and the authors suggest that fractional charges had transferred from tungsten to niobium.

In the same month in 1977, G Galilano, M. Marinelli and G. Morpurgo, from the University of Genoa, published results from their magnetic levitation experiment (*Phys. Rev. Lett.* 38, 1255; 1977). Like Fairbank, Morpurgo and his colleagues had been investigating levitometer techniques for quark searches ever since Gell-Mann's original hypothesis, and indeed had been the first to publish the principles of the method. In their latest experiment, they used small iron cylinders, of mass 2×10^{-7} kg as their samples. The iron is attracted from above by an electromagnet, and a dynamic equilibrium against gravity requires an electronic feedback to the magnet current. However the method has the advantage of operating at room temperature. Vertical electrical plates were used and the cylinders were oscillated horizontally by an alternating potential difference. Again the amplitude is a measure of the residual charge on the samples. Five samples were investigated and no fractional charges were found. The total mass of material in the Stanford and Genoa experiments was quite comparable, about 1 mg or nearly 10^{21} nucleons each. Of course if the Genoa group had also obtained evidence for fractional charges of the required value, the case for free quarks would have been strengthened greatly. Their negative result, however, was not incompatible with the Stanford claims, both on statistical grounds, and because different materials were used. It is conceivable that quarks may have greater affinity to heavier nuclei, in which case niobium (nuclear charge $Z=41$) would be better than iron ($Z=26$), and tungsten ($Z=74$) would be better still. Nevertheless it was clearly possible that one of these difficult experiments was wrong, and in the exchange of

several letters in *Physics Today* during 1977 and 1978, Morpurgo and Fairbank each pointed out the advantages of his own method.

In addition, during 1977 R. Bland, D. Bocobo, M. Eubank and J. Royer at San Francisco State University (*Phys. Rev. Lett.* 39, 369; 1977) examined tungsten directly in a Millikan apparatus using particles formed in an arc discharge between tungsten electrodes. Good measurements were taken on 69 particles. All were found to have zero residual charge to within a standard deviation of just over $0.01e$. However the total tungsten mass was only 3×10^{13} kg or about 2×10^{14} nucleons, and we can only conclude that tungsten is not several million times richer in free quarks than are niobium or iron.

The recent results published by the Stanford group, used an improved version of their apparatus. All three components of possible permanent electric dipoles could now be measured explicitly by moving a relatively large grounded copper sphere to various positions around 1 cm from the niobium sphere, and applying the alternating electric field symmetrically with respect to ground. The possibility of electric field gradients was further reduced by using optically flat and parallel quartz plates. Sphere No 6 which had charge $+1/2e$ in the previous experiment was used again and measured four times with an electric discharge occurring between levitations. Zero residual charges were found on the first, third and fourth measurements and $+1/2e$ on the second measurement. Sphere No 7 which had zero charge previously was used as a calibration during the same cooldown. During a second cooldown in the new experiment, sphere No 7 was used again, together with a new sphere, No 9. This latest sphere showed a charge of $+1/2e$ on each of the two occasions on which its residual charge was measured.

It is difficult to reach a satisfactory verdict on these experiments, and it is likely that most physicists will reserve judgment pending further results. It seems strange that the quarks in the Stanford experiment, if real, should behave in such a volatile manner. On the other hand, if the effect is spurious it is remarkable that the fractional values reported are just what are required for quarks. The experiments are obviously very difficult, but it is not clear from the published letters why so few measurements have been made. It would be useful to have more measurements, and preferably on samples of different sizes in the Stanford apparatus, and in addition, to suspend niobium samples on the iron in the Genoa experiment. □

Fluctuations in abundance of tropical insects

from Robert M. May

ONE tenet of earlier ecological speculation, still to be found in many popular pamphlets about 'ecology' and the environment, is the notion that complex and diverse communities (with many species and a rich web of interconnections among them) are more stable (with individual populations fluctuating less). A corollary is that, in the biologically crowded and species-rich tropics, populations should be more stable. While it is true that many temperate zone animals, particularly insects, do exhibit large population fluctuations, there is not much analogous information about tropical populations. Thus these theoretical ideas have received little in the way of empirical testing.

Recent work has considerably advanced our theoretical understanding of the possible range of relations between diversity and population stability in ecosystems (see for example *Nature* 276, 117; 1978), undercutting any simple notion that complexity, of itself, promotes stability. But the empirical facts have tended to remain largely anecdotal. In Sierra Leone, Owen and Chanter (*J. Entomol.* 46A, 135; 1972) found that a few species of *Charaxes* butterflies had fairly constant abundance, but these authors were concerned to emphasise their experience that most populations of tropical insects fluctuated a lot. In tropical America, Smith (*Carib. J. Sci.* 12, 45; 1972) has shown a moth, *Urania fulgens*, to exhibit dramatic population explosions. Bigger (*Nature* 259, 207, 1976) has reviewed data on some tropical crop pests, suggesting they fluctuate as much as temperate ones. Pursuing "arguments and data to show that tropical populations normally fluctuate no less violently than their appropriate counterparts of higher latitude", Leigh (in *Ecology and Evolution of Communities* Cody and Diamond (eds), Harvard University Press, 1975) showed that the amplitudes of fluctuation of some common vertebrate herbivores (ranging from northern temperate Isle Royale moose and Mt McKinley dall sheep to Serengeti buffalo and wildebeest) showed no consistent tropical-temperate differences. The difficulty is that most of these studies concern one, or at best a few, species, which can be argued to be exceptions.

In this context, a recent paper by

Robert M. May is Class of 1877 Professor of Zoology at Princeton University.

Fig. 1 The annual variability (AV = variance of $\log R$) plotted against the mean value of $\log R$, for various collections of data on insects. The open squares are for tropical insect communities, the solid squares for temperate ones, and the asterisks for (sub)arctic ones; in all cases, all populations are represented by at least five individuals ($NS > 5$).

Wolda (*Am. Nat.* 112, 1017; 1978) does two important things. First, he presents data, collected from light traps, that constitute the best study yet made on the year-to-year fluctuations in abundance of tropical insects. Second, Wolda gives a systematic compilation and analysis of some 138 studies providing information about the average level of year-to-year fluctuation exhibited by groups of tropical and temperate insects.

For his own study, Wolda used three sets of light traps, located at sites in Panama. From the lowland tropical monsoon forest, on Barro Colorado Island in the Panama Canal Zone, he obtained 32,494 individuals that could be classified into Homopteran species (for a total of 565 species) from a ridge site, and 1,538 such individuals (222 species) from a valley site where the light traps were operated less often. The third site was on the edge of a town near Panama City, overlooking second-growth forest, and produced 53,680 classifiable Homopteran individuals (507 species). A few species from orders other than the Homoptera were also included in the overall tropical-temperate comparison, as were unpublished data for Blattidae gathered by Fish. As discussed by Southwood (*Ecological Methods* (2nd ed), Chapman and Hall, 1978), collections from light traps contain biases that make them unreliable indicators of the total number of species in a region, or of the relative abundance of species. Light trap data should, however, pro-

vide a good estimate of the year-to-year fluctuations in abundance of any one given species; Wolda gives several lines of evidence (including independent estimates of abundance from netting) to suggest this is indeed the case for his study.

For each species, Wolda then calculates the ratio, R , that measures the change in abundance from one year to the next: $R = N_t/N_{t-1}$. For a group of species, one then obtains the frequency distribution of values of $\log R$, describing the year-to-year changes in abundance which occur within the group, the mean of this distribution measures the average population change for the group as a whole, and the variance measures the differences among the species. Note that Wolda's 'logR' is the standard 'k-factor' of the pest control literature (see for example, Varley, Gradwell & Hassell *Insect Population Ecology*, Blackwell, 1973). Wolda christens the variance of the $\log R$ distribution the "annual variability", AV, and proceeds to use it to characterise the range of increases and decreases in species abundance within the community under consideration. High values of AV correspond to a wide range of values of $\log R$, with some species showing marked increase in abundance, and others marked decrease, small values of AV correspond to the set of species showing little variation in abundance. Wolda's own data are then analysed in detail, to show *inter alia* that statistical fluctuations arising from small sample sizes introduce relatively little bias if species represented in any one year by less than five individuals are excluded (provided there is information either about many species in any one year, or about a few species for several years).

Wolda condenses the results of his experiments into the AV *versus* the mean value of $\log R$ for the set of Homopteran species, and for a miscellaneous set of other species, at each of his three sites. These results are compared with those of a synoptic compilation of other work. The collections of species in these 130-odd other studies were variously obtained by baiting, beating, emergence traps, light traps, direct observation, pitfall traps, quadrat counting, sweeping, sticky traps, windowpane traps, and other forms of traps. They come from physical environments that may be roughly grouped as (sub)arctic, wet temperate, dry temperate, wet tropical, dry tropical, and a special group for obviously unstable situations (such as migrating moths, or insects invading a newly available area).

Figure 1 summarises the results of AV *versus* mean ($\log R$) for the sites

classified as 'wet': the open squares are for tropical insect collections; solid squares are temperate insects; asterisks are (sub)arctic. Discussing the pattern that emerges, Wolda says "the tropical data in [this figure] are in the same part of the graph as the majority and the best of the temperate data. [The data points based on 100 or more individual values of $\log R$ tend to have AV less than 0.2.] The temperate data scatter more, but there are many more of them. Both the smallest and the largest values of AV are from temperate insects. The conclusion can thus only be that the data suggest rather strongly that tropical insects have, on the average, the same annual variability as have insects from the temperate zone. There is no indication of a greater stability of tropical insects." Wolda sensibly does not subject the data in Fig 1 to any statistical jiggery-pokery to buttress this assertion, and the reader is free to draw his own inferences from Fig. 1; I think Wolda's conclusion is reasonable.

For dry temperate, dry tropical, and 'unstable' collections of insect populations, there are fewer data points. These show more scatter (typically having higher values of AV and mean $\log R$) than the wet environments of Fig 1, and the tropical data are clearly mingled randomly amongst the temperate ones. As we might expect, the AV does show systematic increases in specific 'unstable' instances where the environment is disturbed or newly created. The AV for the community of insects and spiders that colonised the Lauwerszee polder, subsequent to its conversion to dry land in 1969, was 0.64, 0.49 and 0.37 for the years 1967-70, 1970-71 and 1971-72, respectively; this not only shows the predicted decrease as the community becomes more settled, but also is understandably larger than the corresponding AV of 0.10 for an older polder (Meijer *Oecologia* 16, 185; 1974). For aquatic invertebrates upstream of an industrial outlet of cooling water in Britain, AV was 0.18; downstream it was 0.25 (Langford *Hydrobiologia* 47, 91; 1975).

Given that tropical and temperate insect populations show similar levels of fluctuation in abundance under similar environmental conditions, Wolda goes further to claim that "tropical insects are not more to the K end of the r-K continuum of strategies" than their temperate counterparts". I think this goes too far. There are systematic trends in the life history strategies of many groups of animals, including insects, as one goes from the equator to the poles (see for example, Southwood *et al.*, *Amer. Nat.* 108, 791; 1974). Such trends toward more K-ish behaviour among tropical

insects are not inconsistent with tropical insect communities exhibiting levels of population fluctuation comparable with temperate ones; the stabilising tendencies of such K-ash life history strategies can easily be offset by the lower dynamical stability that is characteristic of more complex (species-rich) ecosystems. This view that tropical and temperate communities may manifest similar levels of AV, accomplished by tropical populations exhibiting special features that help offset the intrinsically greater dynamical fragility of a complex system, is clearly a personal one, but it deserves to be considered.

In short, the body of information collected and compiled by Wolda suggests that tropical insect populations, including those from tropical forests, do not show systematically lower fluctuations in abundance than their temperate cousins. Insect populations from relatively dry areas, where the rainfall is low and unpredictable, do tend to fluctuate more, this tendency is, however, equally true for tropical and temperate insects. □

What's special about actin?

from Michael Geisow

THERE is little doubt that actin enables cells literally to shape up to their role in an organised community. Even loners like the amoeba do not dispense with this ubiquitous protein. Although fibrous (F)-actin is most familiar as the protein component of the thin filaments of skeletal muscle, current interests centre on non-muscle actins which are probably present in the cytoplasm of all cells. In non-muscle cells, F-actin forms the microfilaments frequently observed in association with the plasma membrane. Representative structures are the fibrous bundles within cell microvilli and stress fibres apparent in fibroblasts spread on a solid surface. These structures are frequently labile—the major distinction between muscle and non-muscle cells is that the latter have mechanisms for maintaining actin in its non-polymerised state (G-actin). These general observations raise three key questions. In non-muscle cells, what regulates the intracellular distribution of actin filaments and the degree of actin polymerisation? What determinants govern the attachment of actin to the plasma

Third age of quantum chemistry

from Graham Richards

THE earliest quantum mechanical calculations of molecular properties were very crude and hoped only for agreement with experiment within an order of magnitude. The interest in this pioneering work arose from the fact that approximate agreement did provide some insight as to the reasons for the values of measured properties.

A second age depended on the advent of increasingly powerful computers. *Ab initio* calculations of molecular orbital wave functions boomed and continue to fill the scientific literature in many areas. These more accurate calculations are in much closer agreement with experimentally measured parameters. The complexity of the calculation often precludes the use of simple pictorial explanations and the answers cannot be preferred to experiment. Apart from proving the methods, this type of work receives most justification when applied to systems where the experiment is not a viable alternative to computation; perhaps the molecule is unstable or cannot be synthesised.

Now steady improvements in theoretical calculations have led to the dawning of a third age: calculations which are more accurate than experiment or at very least sufficiently accurate to be indispensable for interpretation. An example of such a case is the elegant spectroscopic experiment of Hunziker and his colleagues at the IBM Research Laboratory San Jose (Wendt, Hippler & Hunziker *J. chem. Phys.* 70 in the press).

The experiment concerns the near-infrared electronic absorption spectrum of the *cis* isomer of electronically excited triplet acetylene, formed by mercury-photosensitised reactions of acetylene, ketene and diazomethane. Although aliphatic unsaturated hydrocarbons in their lowest triplet electronic states are important chemical intermediates they have not been studied spectroscopically, in contrast to the widely investigated aromatic triplets. In its lowest triplet excited state acetylene adopts a planar bent

geometry with both hydrogens on the same side of the carbon-carbon bond (*cis*).

The key to identifying the spectrum was the theoretical work of Wetmore and Schaefer (*J. chem. Phys.* 69, 1678; 1978) which showed that the observed features correspond closely with the predictions for the $^3A_1 - ^3B_2$ transition of acetylene. The spectroscopists were able to observe rotational and vibronic structure as well as deuterium isotope effects, again agreeing to a remarkable degree with the *ab initio* theoretical predictions.

An electric dipole transition between the triplet states is allowed for *cis* geometry ($^3A_1 - ^3B_2$) but parity forbidden in the *trans* case ($^3A_u - ^3B_u$) and the two forms are separated by a potential barrier of the order of 1 eV. The spectrum was observed using a photochemical modulation apparatus. With this technique small transient absorptions are observed by phase sensitive detection and reaction rates determined using phase shift measurements. These showed that the lifetime of the transient at 1.35 μm in the acetylene experiments was about 3×10^{-12} s. The principal feature of the spectrum is a single band at 1.35 μm supporting both the calculations and spectroscopic analysis which show that the geometries of the two electronic states are very similar. There is for instance a change in C-C-H bond angle of about 2° .

The formation of the excited *cis* acetylene is particularly efficient using Hg-photosensitised ketene and diazomethane. The suggested mechanism for this process involves the triplet state of methylene, CH_2 , in the reaction

The work represents perhaps a near perfect instance of theory being in harmony with experiment, each aspect vital to the other and the combination much more than the sum of the separate parts.

Graham Richards is a lecturer in the Physical Chemistry Laboratory, University of Oxford.

membrane and to itself to form micro-filament bundles? And last, but most crucial, how are the assembled actin fibres used to generate the diverse types of motion (or tension) with which they are apparently associated?

Very often the most profitable lines of work in complex biological systems have tackled the molecular character of the protein responsible. It is therefore surprising that although many actins

are readily purified in quantity, structural information is sparse. The few amino acid sequences which are known indicate that actin is very highly conserved; there are only 17 changes out of 375 amino acids between mammalian cytoplasmic actin and that isolated from the lower eukaryote *Physarum polycephalum* (Vanderkerckhove & Weber *Nature* 276, 720, 1978). Five of these differences occur at the

amino terminus, which is highly variable in all actins.

Within this framework of close sequence homology, the non-muscle proteins (β and γ -isoactins) differ significantly from muscle proteins (α -actins). Non-muscle actins more closely resemble their counterparts in other species than muscle actins in their own species. There are 25 sequence differences between mammalian muscle and *Physarum* actin. Consistencies in the pattern of amino acid substitutions between the muscle and non-muscle classes of actin suggest that some of the differences reflect functional divergence rather than evolutionary 'drift'. For example, brain, platelet, *Acanthamoeba* and *Physarum* actins all have threonine (moderately polar) at position 129, while heart and skeletal muscle actins substitute valine (hydrophobic).

Slow evolution of amino acid sequence generally implies that a greater-than-average proportion of the polypeptide chain is determinant of biological function. For instance, in the cytochromes *c*, most of the numerous invariant residues are responsible for correct binding of the large, buried haem moiety. Sequence changes between species variants or even class variants of a given protein are usually accommodated at the molecular surface. Between the various actins, however, substitutions of charged (surface) amino acids are rare. In consequence, Vanderkerckhove and Weber point out that evolution of actin surface topography must be subject to unusually rigid constraints. In fact direct experimental support for this contention is provided by the weak immunogenicity of actin and the universal species specificity of some anti-actins.

Conservation of the surface structure of actin makes sense in terms of known functions of the protein. It can form extensive linear and lateral associations to produce F-actin and micro-filament bundles. In non-muscle cells these associations are readily reversible, but they are comparatively stable in muscle cells. Knight and Offer (*Biochem. J.* 175, 1023; 1978) describe a method of chemically cross-linking favourably-disposed cysteine and lysine residues in adjacent monomers of muscle F-actin. This ingenious modification not only offers the opportunity of identifying regions of the actin monomer involved in polymer formation, but may also allow stabilisation of F-actin under a variety of conditions in order to study interaction with other molecules.

Both G and F-actins also associate with unrelated proteins. It has been known for some time that G-actin tightly binds pancreatic DNase I with $K_{app} = 5 \times 10^8 \text{ M}^{-1}$ (Lazarides & Lind-

berg *Proc. natn. Acad. Sci. U.S.A.* 71, 4742; 1974). Rohr and Mannherz (*Eur. J. Biochem.* 89, 151; 1978) report the natural occurrence of this complex in rat pancreatic secretion. The same workers also demonstrate that 5'-nucleotidase (present in rat bile) acts in the formerly intractable G-actin-nuclease complex to produce filamentous actin with the release of active DNase I (*FEBS Lett.* 95, 284; 1978). The interaction between DNase I and actin led to the recognition that G-actin in spleen cells was bound to 'profilin'—a 16,000 molecular weight polypeptide. This complex was identical with a previously reported DNase I inhibitor from spleen. Because the profilin-actin interaction prevented the usual salt-induced polymerisation, this non-muscle actin could be crystallised as a 1:1 complex with profilin under conventional conditions of high ionic strength (Carlsson *et al. J. molec. Biol.* 105, 353; 1976). Similarly, the prospect of 3-D structural analysis of muscle actin was made more likely by the introduction of a non-ionic polymer (PEG) as a means of crystallising G-actin (Oriol *et al. FEBS Lett.* 73, 89; 1977). The reasons for the tight binding of G-actin to DNase I and profilin remain obscure, but may bear on the control of actin polymerisation which operates in non-muscle cells. G-actin also seems to form a polymeric complex with the unique molecule spectrin, a peripheral protein of the cytoplasmic face of erythrocyte membranes. It is not yet certain what the association state of actin is, but evidence favours the monomeric G-form.

F-actin appears to be catholic in its interactions with other cell proteins. Binding to α -actin, myosin, tropomyosin and troponin is established beyond doubt and is further indicative of the degree to which actin's molecular surface must be conserved. In non-muscle cells current reports frequently point to the importance of F-actin as a structure responsive to the distribution of membrane proteins. For example both actin and tubulin were found to co-cap with mouse B lymphocyte membrane immunoglobulin (Gabbiani *et al. Nature* 269, 697, 1977) and with membrane receptors cross-linked by concanavalin A (Toh & Hard *Nature* 269, 695; 1977). Flanagan and Koch (*Nature* 273, 278; 1978) demonstrate that the amount of IgG co-extracted with actin by a myosin-actin affinity technique was proportional to the extent of cross-linked membrane IgG. Murine mastocytoma (p815) cells spontaneously shed plasma membrane from microvilli. In this exfoliated membrane a strong association exists between the histocompatibility antigen H-2 and actin (Koch & Smith *Nature* 273, 274; 1978). It is significant

that the H-2 antigen is known to be a transmembrane protein and that both IgG and H-2 continue to associate with actin in the presence of detergents. Analogously, 5'-nucleotidase, freed from its membrane sites by the detergent action of bile salts, can also interact with actin in the form of its nuclease complex.

The strong implications of all these studies is that the extent of membrane attachment and possibly the degree of assembly of F-actin as a cytoskeletal element is sensitive to the state of association of a variety of membrane proteins. The stability of preformed membrane protein-actin associations after solubilisation from the membrane suggests direct binding of actin to membrane proteins by a transmembrane event. However there is as yet no unambiguous demonstration of direct interaction of actin with a transmembrane protein and most authors admit the possibility of intermediate components. The three questions posed initially have not been solved, but complete answers to some of them cannot be far off. It would be timely if the first answer to reach the press was the crystal structure of the source of all the problems; G-actin. □

Polymer mixtures

from Paul Calvert

A RULE which is taught in basic polymer courses is that polymers do not dissolve in one another because the entropy of mixing of large molecules is essentially zero. A review by Sonja Krause in 1972 (*J. macromolec. Sci., C*, 7, 251) listed several hundred pairs of polymers of which only about 10% were compatible and this is probably an overestimate. With the current stress on modifying existing synthetic polymers rather than manufacturing new ones, studies on 'polymer alloys' have become fashionable and compatible systems are of real interest.

The basic Flory-Huggins theory of polymer solution thermodynamics, extended by Flory to include free volume effects, has been applied to polymer mixtures by McMaster of Union Carbide and now more simply by Patterson and Robard of McGill (*Macromolecules* 6, 760; 1973; 11, 690; 1978). The essence of the argument is that the entropy of mixing in a solution is proportional to the number of molecules and so becomes very small for high molecular weight polymers whilst

Paul Calvert is a Lecturer in the School of Molecular Sciences, University of Sussex.

the free energy of interaction between chains depends only on the volume of the system and so dominates at high molecular weights. Free volume differences give rise to small increases in free energy when similar liquids are mixed, so mixtures of similar polymers, for instance two polyolefins, will be incompatible. In order for a homogeneous solution to form there must be some preferential bonding between the unlike chains, such as hydrogen bonding or dipole interactions. This is characterised by a negative interaction parameter χ . Unfortunately this does not help a great deal to explain why some polymers are compatible. Although it seems plausible that some specific 1:1 dipole interactions could take place between polyvinyl chloride (PVC) and polyesters such as polymethyl methacrylate (PMMA) or poly(ϵ -caprolactone), it is hard to see what interaction makes poly(2,6-dimethyl 1-4-phenylene oxide) (PPO) compatible with polystyrene (PS). Such things can always be explained but not in a way that has any predictive value.

The experimental basis for compatibility is also rather weak. Early studies were done on the basis that cloudy samples were phase-separated whereas transparent ones were compatible. In fact transparency may just represent fine scale phase-separation or a refractive index match between the phases. Electron microscopy of stained samples can be used but this is limited to a scale of 100 Å or more and depends on having a good stain. The other approach is to observe the glass transition temperature(s) of the sample. Two transitions close to those of the pure polymers implies separation whereas one intermediate transition is taken to show compatibility. However this only works if the two starting polymers have transitions 100 °C or more apart and is misleading if phase separation or dissolution takes place during heating. There is also considerable doubt as to whether two transitions will be seen if separation is on a fine scale. Thus we can demonstrate phase separation but cannot demonstrate compatibility. It is also unclear whether complete dissolution can take place or if all mixtures contain at least local heterogeneity.

Kwei, Wang and Nishi of Bell Telephone Laboratories have looked at polystyrene-poly vinyl methyl ether mixtures by microscopy, vapour sorption and diffusion, and NMR (*Macromolecules* 7, 667; 1974; 8, 227; 1975). They were able to outline a phase diagram with a lower critical temperature above which separation occurred and found a suitably negative χ factor at 30 °C although χ was dependent on the mixture composition which is rather unsatisfactory. These bulk

measurements suggest homogeneous mixing but two T_g values were observed by wide-line NMR implying that two types of environment are present and hence heterogeneity. One of these polymers performed the interesting trick of going from cloudy to transparent to cloudy again as it was heated to 150 °C.

The polystyrene-polyphenylene oxide system is of technical interest since PPO is usually modified by addition of PS which reduces the melt viscosity so that the polymer can be processed. Workers at General Electric and at University of Massachusetts have investigated mixtures of PPO with styrene-*p* chlorostyrene copolymers (*Macromolecules* 7, 902; 1974; 11, 151; 1978). Phase separation occurs when the copolymers contain less than 33% styrene. A single glass transition was seen in the compatible systems but this broadens significantly close to the critical composition, dielectric loss peaks broaden similarly, suggesting that there are large local composition variations before phase separation occurs.

Another interesting system is polyvinylidene fluoride (PVF2)-polymethyl methacrylate which has been studied at Bell Telephone Laboratories and at Groningen (*Polymer* 19, 173; 1978; *Macromolecules* 9, 603; 1976; 11, 766; 1978). PVF2 crystallises out of the

homogeneous mixture so that analysis of its melting temperature, allows a χ parameter to be determined. It is small and negative as expected. PVF2 is compatible with isotactic, syndiotactic and atactic PMMA whilst PVC is incompatible with isotactic PMMA but miscible with the other two up to a 1:1 ratio of PVC to PMMA monomer units (*Polymer* 16, 201; 1975). This indicates that some specific chain pairing is occurring which depends on the conformation of the PMMA and that these pairs are miscible with PVC but separate in excess PMMA.

Thus there is evidence in compatible systems for local segregation of each polymer and/or pairing of unlike chains. The structure of these materials must have much in common with that of block and graft copolymers where each chain is itself a mixture of two or more polymers. The 1977 ACS Symposium on Polymer Alloys (eds Klempner & Frisch, Plenum, 1977) shows the extent of industrial interest in these systems. As well as the familiar use of grafted elastomer phases to toughen brittle plastics it should be possible to improve solvent resistance, fire retardancy and oxidation resistance. However perhaps the most interesting possibility is the development of two phase or compatible polymers for selectively permeable membranes □

Complexities of vitamin D metabolism still increasing

from Alastair Hay

THERE is no disputing the activity of the kidney metabolite of vitamin D₃, 1,25(OH)₂D₃. It is an active hormonal form of the vitamin essential for calcium and phosphorus absorption from the gut, and mobilisation of calcium from bone. There is dispute, however, as to whether it is the only hormone of vitamin D. The second contender for hormonal status is the other kidney metabolite 24,25(OH)₂D₃. It has been suggested (Kanis *et al. Brit. Med. J.* 1, 1382; 1978) that this metabolite may also be a calcium-regulating hormone in man.

The arguments over the significance of these metabolites for calcium regulation were two of the themes considered at a recent workshop* on vitamin D.

To reinforce the point that 1,25(OH)₂D₃ is important, values for this metabolite were quoted for an array of clinical conditions. In contrast, 24,25(OH)₂D₃ measurements were less numerous but perhaps more contro-

versial. Serum measurements of 1,25(OH)₂D₃ were reported by B. Lund (Frederiksberg Hospital, Denmark) to be two to three times higher than normal in patients with hyperparathyroidism and acromegaly, and to be very high (~200 pg ml⁻¹) in children under 2 years of age. Values for 1,25(OH)₂D₃ in children fell progressively with increasing age but rose again during the adolescent growth spurt. Acromegaly is a syndrome in which there is an overproduction of growth hormone. This, together with the observations made in children, suggested to Lund that growth hormone is indeed involved in the regulation of 1,25(OH)₂D₃ production.

Lund reported low serum measurements of the metabolite in patients with senile osteoporosis and femoral neck fractures. Similarly in subjects with hypoparathyroidism he observed serum values of 20 pg ml⁻¹ compared with the 30-35 pg ml⁻¹ of control subjects. Serum values of 20 pg ml⁻¹ were also noted in subjects with kidney transplants M. R. Haussler (University of Arizona Medi-

*The 4th Workshop on Vitamin D was held in Berlin on 18-22 February, 1979.

cal College) also reported some low serum $1,25(\text{OH})_2\text{D}_3$ values. He measured 10 pg ml^{-1} in subjects with D-dependent rickets but in D-resistant rickets the measurements were 32 pg ml^{-1} and were similar to control subjects—a surprising finding, for the low serum phosphate levels in these subjects might have been expected to produce higher $1,25(\text{OH})_2\text{D}_3$ values. Nevertheless, Haussler reported that treatment with $1,25(\text{OH})_2\text{D}_3$ cured the rachitic lesions of D-resistant rickets and was similarly effective in the treatment of a patient with tumour-induced osteomalacia with a serum $1,25(\text{OH})_2\text{D}_3$ of $17\text{--}18 \text{ pg ml}^{-1}$.

One of the more curious twists to the $1,25(\text{OH})_2\text{D}_3$ story is Haussler's observation that female spawning trout have levels of the metabolite in excess of 75 pg ml^{-1} . The metabolite is said to be important for phosphate regulation in the eel (McIntyre *et al.* *J. clin. Endocr.* **5**(Supp.) 85S; 1976) yet neither D. R. Fraser (see *News & Views* **273**, 426; 1978) nor M. R. Holick (Massachusetts General Hospital) has been able to detect this or other dihydroxy metabolites of vitamin D_3 in fish receiving isotopically-labelled vitamin. In view of the specificity of Haussler's assay many would assume that it is indeed $1,25(\text{OH})_2\text{D}_3$ he is measuring. However, the observations of Fraser and Holick suggest that it may not be this metabolite, but perhaps one of a closely related structure.

Several authors stressed that $24,25(\text{OH})_2\text{D}_3$ may be important for calcium action in bone but not everyone is convinced that it is. S. Edelstein (Weizmann Institute, Israel) presented evidence that $24,25(\text{OH})_2\text{D}_3$ seems to be necessary for endochondral ossification of cartilage and bone. J. Kanis (University of Oxford) says the metabolite increases calcium retention in man and that this may be associated with increases in skeletal calcium accretion. And H. M. Malluche (University of Southern California School of Medicine) reported that in chicks neither $1,25(\text{OH})_2\text{D}_3$ nor $24,25(\text{OH})_2\text{D}_3$ would maintain bone integrity on their own, but that both metabolites were required for this purpose, a view put forward earlier by Ornoy *et al.* (*Nature* **276**, 517; 1978). S. W. Stanbury (University of Manchester) questions whether $24,25(\text{OH})_2\text{D}_3$ is so important for calcification of bone. In subjects treated for vitamin D deficiency with $1,000 \text{ IU}$ of $^3\text{H}\text{-D}_3$ Stanbury observed $1,25(\text{OH})_2\text{D}_3$ and $25,26(\text{OH})_2\text{D}_3$ in the serum in the first few days but no $24,25(\text{OH})_2\text{D}_3$. In some cases $24,25(\text{OH})_2\text{D}_3$ was not seen until 6 or 10 days after the start of vitamin D therapy. In view of the fact

that changes in the calcification front of bone are seen 3–5 days after the administration of vitamin D, Stanbury queried whether $24,25(\text{OH})_2\text{D}_3$ was the principal metabolite responsible for mineralisation. Could it be that $25,26(\text{OH})_2\text{D}_3$ is a more important metabolite for mineralisation he asked. Stanbury also reported that serum levels of $25,26(\text{OH})_2\text{D}_3$ were $0.5\text{--}0.8 \text{ ng ml}^{-1}$ and about a third of the $24,25(\text{OH})_2\text{D}_3$ values in D-replete subjects. J. L. H. O'Riordan (Middlesex Hospital) on the other hand found much lower $25,26(\text{OH})_2\text{D}_3$ values ($178\text{--}336 \text{ pg ml}^{-1}$ using a radioimmunoassay. The antibody used by O'Riordan has been developed for use in measuring $1,25(\text{OH})_2\text{D}_3$, however, in view of its high, and as yet unexplained, cross-reactivity with the other dihydroxymetabolites of vitamin D_3 it is being used to measure $25,26(\text{OH})_2\text{D}_3$.

Measurements of $24,25(\text{OH})_2\text{D}_3$ still tend to be controversial chiefly because of the twofold difference reported for UK and US subjects. C. M. Taylor (University of Manchester) says that $24,25(\text{OH})_2\text{D}_3$ values are about 8% of the $25(\text{OH})\text{D}_3$ values whereas Haddad *et al.* (*Arch. Biochem. Biophys.* **182**, 390; 1977) claim that in the US they are about 20%. Furthermore, Taylor says that there is no detectable $24,25(\text{OH})_2\text{D}_3$ in anephric subjects whereas Haddad, H. F. DeLuca (in *Proc. VII International Congress of Nephrology*, Montreal, 1978) and R. L. Horst (University of Wisconsin) say there is. However, it seems that these differences between the UK and US laboratories may not be irreconcilable. There are two possible explanations.

The first is one of three new metabolites of vitamin D_3 reported by H. F. DeLuca (University of Wisconsin) one of which comigrates with $24,25(\text{OH})_2\text{D}_3$ on Sephadex LH 20 chromatography, but which is separated from it on high performance liquid chromatography (HPLC). The metabolite is a lactone involving carbons 23 and 25 of the D_3 side chain. Although the lactone accounted for a sizeable portion of the $24,25(\text{OH})_2\text{D}_3$ peak on Sephadex when chick serum was used, Horst said that he had not seen it in human plasma. The other alternative is the $25,26$ -dihydroxymetabolite of vitamin D_2 which we (Hay & Jones *Clin. Chem.* **25**, 473; 1979) have reported also to comigrate with $24,25(\text{OH})_2\text{D}_3$ on Sephadex LH 20. Taylor confirmed this observation, but reported that this comigration also occurs on HPLC. It seems, therefore, that where vitamin D_2 is consumed in appreciable quantities in the diet—as it is in the US—that $25,26(\text{OH})_2\text{D}_2$ may be assayed together with $24,25(\text{OH})_2\text{D}_3$. This D_2 metabolite may also account for the $24,25(\text{OH})_2\text{D}_3$ values recorded in anephric subjects in the US.

Measurements of both $25,26(\text{OH})_2\text{D}_2$ and $24,25(\text{OH})_2\text{D}_3$ will be required before this can be answered definitively. Perhaps when these results are available the UK and US results will be seen to agree and investigators can turn once more to elucidate the actual functions of the $24,25$ and $25,26$ dihydroxy metabolites of vitamin D, and indeed that of all the other metabolites discovered over the past year, for it is quite clear that many doubts exist about some of the theories put forward so far. □

A hundred years ago

A STRIKING and highly promising line of research has been recently adopted by Mr. Muybridge, of San Francisco, at the instance of Governor Stanford, viz., the instantaneous photography of animals in motion. Some of his earlier photographs of a fast-trotting horse presented attitudes wholly unexpected, and they were even thought absurd. The method latterly adopted seems to have been making the horse trot or gallop past twelve cameras, arranged in series, and by breaking threads stretched across its path, release an electric current, which effected exposure of the plates. Thus the flying steed was obtained in every position. Mr. Muybridge gave public exhibitions of what had been done. The small negatives were magnified into life size, and projected on a screen, so that every motion was visible. These exhibitions do not seem to have been appreciated by the San Franciscans. The *Scientific American*, however, and afterwards *La Nature*, have published cuts taken from the photographs, and much general interest has been awakened in these researches. Among those specially interested is Prof. Marey, who desired to be put in communication with Mr. Muybridge, as he wanted to ask his aid in solving certain physiological problems, so difficult to solve otherwise; e.g., questions connected with the flight of birds. He had been dreaming of a kind of photographic gun, to seize the bird in an attitude or series of attitudes of flight. What beautiful zootropes, too, might be had! Mr. Muybridge's cartoons representing the fast gallop give a key to the breaking down of so many horses. It appears as though one foreleg had to sustain the whole weight of horse and rider while the body is moved along five feet. And just before the foot is raised, a perpendicular from it would strike the back of the saddle; so that there is immense leverage, the centre of gravity being thrown so far forward of its support, and the tendons must have a terrible tension. These inquiries are being further developed by the liberality of Governor Stanford and the skill of Mr. Muybridge, and valuable results may doubtless be looked for.

Ancient crustal metamorphism at low p_{H_2O} : charnockite formation at Kabbaldurga, south India

A. S. Janardhan

Department of Geology, Mysore University, India

R. C. Newton & J. V. Smith

Department of the Geophysical Sciences, University of Chicago, Illinois 60637

Arrested charnockitic conversion of amphibolitic gneiss at Kabbaldurga, Karnataka State, south India, was studied mineralogically. Iron-rich pyroxenes were generated from amphibole in patches and stringers without melting. The dark colour of charnockite arises from numerous tiny veins of chlorite and manganese-bearing calcite, particularly in feldspars. The metamorphism was effected by very local, mainly grain-boundary, migration of volatiles low in H_2O , and probably dominantly CO_2 . This was followed by vein alteration at lower temperatures from volatiles richer in H_2O . The volatiles are ascribed to massive liberation from the mantle in upwelling areas, and this may have been an important process in the evolution of the deep continental crust.

CHARNOCKITE is a widespread orthopyroxene-bearing granitic rock in the Precambrian shield of southern India¹. It commonly has dark green to brown coloured fresh surfaces². Closely related intermediate to basic rocks at the Madras type locality were called the 'charnockite suite'². The abundant global distribution of the charnockite suite in Precambrian terrains is a key issue in discussions of crustal evolution³.

Charnockite apparently derives from both igneous and sedimentary rocks⁴⁻⁶ by a particular kind of metamorphism. The associated pore fluids must have been low in H_2O because the association orthopyroxene-potassium feldspar is limited to H_2O pressures below 700 bar, being replaced by either biotite-quartz or melting at higher H_2O pressure⁹. Carbon dioxide is a probable diluent: primary CO_2 -rich inclusions are characteristic of granulites¹⁰ and charnockites¹¹. The present mineralogical study of arrested charnockite development at a southern India locality shows that conversion of amphibolitic gneiss to charnockite was effected without melting by grain-boundary migration of low p_{H_2O} volatiles, presumably mainly CO_2 . A copious, possibly primitive, source of volatiles, such as a mantle plume or diapir, must be invoked.

Partial conversion of Archaean (~2,700 Myr) amphibolitic gneiss to charnockite at a quarry in Kabbaldurga, Karnataka^{12,13}, presents the opportunity for microanalytical study of amphibolite to granulite transition in both acid gneisses and basic enclaves.

The Kabbaldurga and similar occurrences in southern Karnataka¹⁴ may be the northernmost 'front' of charnockite

development which culminates in the great massifs of the Biligirirangan and Nilgiri hills. All features of the cratonic portion of Karnataka, including the Dharwar schists and younger granites, as well as the dominant Peninsular gneiss, can be traced southward as relics into the charnockite massifs.

Such large-scale conversion to granulite would culminate in a stable, refractory, and inert continental mass low in the incompatible and heat-producing elements¹⁵.

Mineralogical changes in charnockitisation at Kabbaldurga

The altered gneiss has the characteristic dark colour of charnockite and contains hypersthene in the most reconstituted specimens. Diffuse patches and stringers of charnockite, from a few centimetres to metres across, partially or completely obliterate the gneissic foliation and strongly suggest very local action of volatiles, whose access is controlled by shearing or other deformation. All stages of the amphibolite to granulite conversion occur in both the dominant acid gneiss country rock (Peninsular gneiss) and basic enclaves which are undoubtedly dykes of more than one generation, variously contorted and boudinaged. Rock analyses¹⁴ of unaltered gneiss and completely charnockitised gneiss (Table 1), show little change in bulk composition during the process. A slight depletion in K_2O may be suggested. That some basic dykes have conspicuous charnockite selvages might indicate metasomatic interchange between acid and basic rocks as a primary cause of the conversion, except that many dykes, although partially converted to granulite, have no such marginal alteration and some have it only on one side. Channelling of volatiles by less pervious basic horizons seems more probable.

Various degrees of conversion of amphibolitic to granulitic mineralogy are identifiable macroscopically and in thin section in both acid gneisses and their basic inclusions. A few specimens show some metasomatic changes related to charnockite development.

The least-altered acid gneisses are quartz-feldspar rocks with thin subsidiary mafic bands, mostly biotite-rich, but some with both green-brown hornblende and biotite. Magnetite and apatite are ubiquitous accessories. The potassium feldspar is deformed microcline with mottled and strained cross-hatched twinning and exsolution. Antiperthitic oligoclase shows strain-induced albite twinning. Undulatory quartz tends to be lenticular. Oligoclase-quartz myrmekite occasionally marks triple junctions of feldspars and quartz.

The first stages of alteration are signalled in hand-specimen by a dark greenish-brown discoloration of the larger, normally white, feldspar grains. In more advanced stages, the rock as a whole assumes a dark mottling in feldspar-rich portions with some interruption of gneissic banding. In thin section, the minerals are normal except for enhancement of strain effects. Feldspar grains are conspicuously laced with very thin greenish veinlets, which sometimes cut across grains but as often follow grain boundaries. Little change in mineralogy is evident.

At extreme alteration, the hand-specimen is typical dark-brown charnockite. All gneissic texture is gone, and hornblendes and biotites are smaller and fewer. Orthopyroxene appears abruptly in large bent grains whose margins are indeterminate because of late alteration to a dark-red, fine-grained material. Therefore, no clear-cut evidence of the relationship of orthopyroxene to biotite and hornblende exists, although these minerals presumably were its precursors. The orthopyroxene commonly has fine exsolution lamellae and about 10° of inclined extinction and is pleochroic in pale pink and green. Orthopyroxene is most abundant in mafic bands associated with large magnetite grains with quartz inclusions and intergrown ilmenite, but occasional large isolated grains are surrounded by quartz and potassium feldspar.

The thin greenish veinlets are more abundant in the most charnockitic specimens. Many feldspar grains are laced with them, and some cut across quartz grains. Many grains are enveloped by veinlets (Fig. 1), which occasionally open to tiny pods of birefringent material. The veinlets are accompanied by innumerable very brightly birefringent specks.

The dark colour of Madras charnockites was attributed¹⁶ to many apparently similar greenish veinlets cutting and enveloping feldspars. Several hours' contact with warm HCl bleached the charnockite to the appearance of a granite, undoubtedly due to removal of vein material. Chlorite was suggested as the vein filler¹⁶, and some iron loss has been observed after leaching. Qualitative microanalysis of vein material has shown major iron content¹⁷.

The basic inclusions show a more gradual progression to granulite mineralogy. In little-altered specimens the assemblage is green-brown hornblende, oligoclase or andesine and quartz, with smaller amounts of biotite, some of which is probably retrogressive. Diopside first develops in fine-grained symplectites with plagioclase marginal to large hornblende grains.

Hornblende relics in symplectite patches are optically continuous. Various stages of symplectite coarsening culminate in equigranular diopside-hornblende-plagioclase rocks. Veining of plagioclase is common, and large hornblende crystals are frequently cut by coarse biotite-calcite veins.

A few samples show strong metasomatic interaction. Gneissic contacts with granulitised metabasites may be converted to plagioclase-hornblende-diopside-quartz rocks with interstitial potassium-feldspar and typical dark charnockitic appearance. A biotite-rich altered dyke-rock has abundant large potassium-feldspar porphyroblasts associated with diopside. No hornblende is present. This dyke of ~1 m thickness has a 1 m-wide charnockite sledge on one side only. The metamorphic fluids were apparently able to transport potassium.

Microanalytic methods and results

Minerals were analysed with a ARL electron microprobe with a solid-state energy-dispersive system. Beam spot-size was 1 µm and beam current was 60 nA at 15 kV accelerating voltage.

The mafic minerals (Table 1) are richer in iron than those of the Madras type locality^{4-6,18}. The Fe/Mg ratio is higher for the minerals of the gneisses than for the basic rocks. The orthopyroxene (Fs₃₃) has a greater Fe/Mg ratio than any of the other mafic minerals, as was found for the Madras charnockites¹⁸. Note the high CaO and MnO contents of orthopyroxene. Biotite and hornblende become slightly but definitely more magnesian when orthopyroxene occurs in the acid rocks. No such change is evident as diopside appears in the basic rocks. Symplectitic diopside is not different from coarser, recrystallised diopside. The plagioclases do not change from An 27-35 as pyroxene develops in the acid rocks. Primary plagioclase in the basic rocks has a similar range with some slight normal zoning of large crystals. The symplectitic plagioclase in As 33 (Table 1) is An 24, compared to An 31 for the coarse primary plagioclase. Other than the slight zoning of some plagioclase, no significant zoning of minerals was found, thereby indicating thorough attainment of local equilibrium.

The thin greenish veins were scrutinised closely. The traces of extremely thin veins on polished feldspar surfaces gave significant iron and magnesium analyses, although the dominant contributor was wall-rock feldspar. Occasionally, a tiny speck of carbonate or chlorite in a vein gave practically uncontaminated

Fig. 1 Grain-margin veinlet, separating twinned plagioclase from quartz. Note tiny, brightly birefringent specks in veinlet, and bending of plagioclase twin lamellae. Most charnockitised gneiss (N3). Width of photo: 0.7 mm. Partially crossed polars.

analyses. Rare pods of chlorite in thicker veins gave good analyses. The Fe/Mg ratios of heavily contaminated analyses were the same as for the pod analyses, and the veins must contain the same kind of chlorite as the pods, plus calcite. The chlorite is an iron-rich, low-aluminium variety and the calcite is manganese-bearing (Table 1). Plagioclase immediately adjacent to a vein is moderately to highly albitised, but without recrystallisation. Potassium feldspar undergoes an antipathetic reduction in sodium within a few mm of a vein to a nearly sodium-free variety. Unusual mineral specks in the veins were rich in phosphorus and vanadium.

Conclusions and discussion

Several conclusions were drawn about the charnockite-forming event seen arrested in progress at Kabbaldurga.

(1) The granulite metamorphism involved localised action of volatiles low in H_2O and, by implication, rich in CO_2 . No concomitant large changes in temperature or pressure were required. The pyroxenes were generated from amphibole without any visible evidence of partial melting. Myrmekitic intergrowths at quartz and feldspar junctures are virtually devoid of K_2O and cannot be a partial melting product¹⁹. Compositions of co-existing mafic minerals are essentially unchanged when pyroxene appears, suggesting no major change of physical conditions. Slow migration of H_2O -poor volatiles could well have been controlled by shearing, or the locations of fold hinges or other deformational features, but strong temperature differences over spaces of a few metres could not have been produced by the migrating gases. Such action of reduced H_2O activity in metamorphic fluids at more or less constant temperature and pressure was invoked to explain the regional amphibolite to granulite transition in southern Norway²⁰. In the south Norway granulite terrain, as in many others, the primary fluid inclusions of minerals are dominantly CO_2 -rich and very low in H_2O (ref. 10).

(2) The event was at relatively high level. Unfortunately, mineral assemblages in the acid or basic rocks place few controls on temperature and pressure. However, absence of garnet gives

an upper limit of ~9 kbar for acid compositions if temperatures in the upper end of the amphibolite range, 600–700 °C, are appropriate²¹. The orthopyroxene is not rich enough in iron to be useful in orthopyroxene–olivine–quartz barometry²². The ratio of tetrahedral aluminium to total aluminium in hornblende is 0.79 in metabasite AS 33 and 0.31 in acid charnockite N3 (Table 1), compared with an average of 0.80 for hornblendes co-existing with biotites in the low-pressure granulites of the southern Yilgarn Block in Western Australia²³. Aluminium is low in pyroxenes. Three to five kbar may be appropriate for the Kabbaldurga granulites.

(3) The waning phases of the metamorphism were characterised by cooler solutions, richer in H_2O , confined to the same localised channelways. Chlorite and manganese-calcite in the veins indicate lower-grade mineralisation than the pyroxene-forming event. Qualitatively, the assemblage is lower-temperature than amphibole + epidote + vapour, and has an intermediate CO_2/H_2O ratio, bounded by ankerite and epidote for CO_2 greater than about 50% of the vapour²⁴.

The veinlets must be related intimately to the pyroxene-producing metamorphism because of the strict correspondence between abundance of veins and the appearance of pyroxene, both in acid and basic rocks. Unaltered gneisses a few yards away from heavily charnockitised gneisses do not have the veins. Even partially charnockitised gneisses in which feldspars are macroscopically discoloured have relatively few veins.

From these conclusions, the picture emerges of copious streaming of low- H_2O , presumably CO_2 -rich solutions, especially along pathways created by deformation. Water is purged and, with it, the minor incompatible elements normally resident in amphiboles, micas and epidote¹⁵. Temperatures may be elevated over broad areas, but gas-streaming is unlikely to raise temperatures significantly on a very local scale. Deeper portions of the crust are converted to refractory granulite. Perhaps there is a crustal level above which, for reasons of low temperatures and readily available H_2O , the process is not operative, and Kabbaldurga is a critical horizon. Such a picture accords with the depth-zone relationship of metamorphism proposed for southern Karnataka¹⁴, culminating in the extreme south with the deep-crustal charnockite massifs.

What is the origin of the postulated CO_2 -rich solutions? Calc-silicate rocks are locally abundant in association with charnockite terrains in the southern Indian shield, and may represent former carbonate rocks. Some may be linked to charnockite development, although it is difficult to see how occasional carbonate horizons could account for charnockite development on such a vast scale as the Nilgiri massif, for instance. No calc-silicate rocks crop out in the Kabbaldurga area. Graphite-bearing rocks are common in the Precambrian, but reaction of graphite with a pore water would produce a vapour which is at least 50% H_2O (ref. 25); amphiboles could not dehydrate in such a water-rich vapour without widespread melting. Primitive sources of CO_2 are increasingly invoked to convert large portions of the continental crust to granulite^{26,27}; ascending mantle convection 'plumes' may be the answer. If these were active in the Precambrian^{28,29}, a volatile phase of initially primitive CO_2/H_2O ratio, believed to be about 3:1³⁰, would be expelled by mantle dehydration and decarbonation. During invasion of the lower continental crust the H_2O component should cause widespread melting and be filtered out, leaving CO_2 -rich ascending solutions. If geothermal gradients were quite high, as expected over the plume, a P - T field of scapolite mineralisation may be avoided³¹ and the CO_2 could continue upward to drive out water from the overlying crust. During the cooling phase of the process, H_2O might again be released by crystallisation of granitic melt at deep levels. The H_2O might mix with CO_2 still coming off the mantle plume or liberated by decarbonation or scapolite conversion to zoisite. These more H_2O -rich solutions would then follow the earlier H_2O -poor solutions, quite plausibly along the same channelways, and could have deposited the chlorite–calcite vein assemblage. Alternatively, heavy CO_2 input might 'swamp' H_2O

resident in the crust during the height of the activity, but be insufficient to lower the H_2O fraction to less than about 40% of the total during the waning stages. Whatever the exact mechanisms controlling vapour composition, combined petrographical and geophysical field work, as, gravity or magnetic surveys, should be useful in implicating or exonerating a mantle diapir as a source of the vapours.

High magnesia liquids as the parental magma for ocean floor basalts

Don Elthon

Lamont-Doherty Geological Observatory of Columbia University and the Department of Geological Sciences, Columbia University, Palisades, New York 10964

The primary melt segregating from the upper mantle beneath an oceanic ridge is shown to contain ~18% MgO. Whereas these primary liquids are capable of generating the petrological features of the oceanic crust, this is not possible for tholeiitic basalts with 9–11% MgO which are highly fractionated. Compositions of liquids ranging from primary melts to high calcium picrites from the Tortuga ophiolite complex, Chile, are reported.

FOR several decades, the origin and diversity of basaltic rocks has been a foremost problem in igneous petrology. After Bowen¹ designated basalt as a primary magma which has risen to the Earth's surface chemically unmodified from its origin in the upper mantle, the predominant opinion among petrologists has been that basalts are primary mantle melts or have undergone only minor degrees of chemical modification during their ascent to the Earth's surface. In contrast to this hypothesis, O'Hara's^{2,3} review of pertinent phase equilibria in natural and synthetic basaltic systems led to the conclusion that basaltic magmas must be the result of advanced degrees of fractional crystallisation, especially at low pressures.

A major obstacle to reconciliation of these two opposing views on basalt genesis is that while phase equilibria indicate that basalts are highly fractionated, the overwhelming abundance of basalts stands in stark contrast to the complete absence, in the oceanic basins, of the proposed picritic magma of O'Hara. As a result, the concept of ocean floor tholeiitic basalt as a primary magma remains as a well accepted, albeit *ad hoc*, hypothesis.

The recent discovery of MgO-rich dykes representing liquid compositions in the Tortuga ophiolite complex, Chile, necessitates a re-evaluation of the nature of the genetic link between 'primitive' ocean floor tholeiites (9–11% MgO) and the upper

mantle. From several independent lines of reasoning, it is possible to demonstrate that magmas with ~18% MgO are primary mantle melts and the parental magmas for relatively evolved basalts with 9–11% MgO.

Composition of the oceanic crust

Ophiolites, as remnant sections of oceanic or marginal basin crust, can provide numerous constraints on the nature of magmatic evolution at a spreading ridge. A complete ophiolite sequence consists of a wide variety of igneous lithologies whose internal relationships have been described elsewhere^{4–6}.

From published data in the Vourinos ophiolite⁷, the Quebec ophiolites⁸, and the Newfoundland ophiolites⁹ as well as my unpublished data from the Tortuga ophiolite, Chile, a petrological columnar section of the oceanic crust has been constructed (Fig. 1). The thicknesses of the various petrological divisions have been constrained from geophysical data¹⁰ and measured sections in ophiolites^{7,8,11}.

An important chemical feature of the oceanic crust is that the crust becomes more enriched in ferromagnesian minerals, with increasing depth. The fractional crystallisation of ferromagnesian minerals from the magma results in the accumulation of olivine, pyroxene, plagioclase, and spinel in the magma chamber, with the extrusion of evolved basaltic liquids onto the floor of the ocean. This results in a mineralogical and chemical layering of the oceanic crust for which, excluding volumetrically minor trondhjemites and other silicic liquids, the most differentiated portion (with highest FeO/MgO) is the sheeted dykes and pillow lavas. Thus, even those sheeted dykes and pillow lavas with 9–11% MgO have undergone significant fractional crystallisation, as predicted by experimental work², and their compositions have been chemically modified since separation from the upper mantle.

Indirectly, the composition of the parental magma separating from the upper mantle can be estimated from Fig. 1 and analyses

Fig. 1 A columnar section of the oceanic crust constructed from lithologies observed in ophiolites. The thicknesses of various lithological units have been constrained from measured sections in ophiolites and geophysical data. See text for details.

of rocks from the Tortuga ophiolite (Table 1). (The term parental rather than primary magma is used here to include the possibility of sub-Moho fractionation which may occur locally.) The bulk composition of the oceanic crust, used here to include all of the igneous rocks above the 'residual' harzburgite, must be equal to the composition of the parental magma as it enters the magma chamber before its extended history of fractional crystallisation and magma mixing, which result in the chemical and mineralogical layering observed in ophiolites (Fig. 1). It is critical while estimating the composition of the oceanic crust to include not only the fractionated magmas which erupt onto the ocean floor in the form of pillow lavas, but also the crystals which have accumulated within the magma chamber.

For these calculations, the oceanic crust can be divided into three sections: (1) pillow lavas, sheeted dykes, and intrusive diabases representing liquid compositions extracted from the upper portions of the magma chamber; (2) cumulate clinopyroxene-bearing gabbros with minor, associated leucogabbros, ferrogabbros, olivine gabbros, two-pyroxene gabbros, and troctolites; and (3) cumulate ultramafic and transition-zone lithologies. The composition of the average sheeted dyke in the Tortuga complex (D. E., unpublished data) is used as the representative composition for the pillow lava-sheeted dyke-intrusive diabase section of the oceanic crust. A comparison of the average sheeted dyke in Tortuga with the average Atlantic Ocean tholeiite glass¹² and the average FAMOUS glass¹³ demonstrate the chemical similarity of the Tortuga ophiolite with oceanic crust (see Table 1). As a model composition for the clinopyroxene-bearing gabbros (with the minor constituents described earlier) the average composition of the 'gabbros' from the Tortuga complex are used (D.E., unpublished data). These are genetically related to the dyke compositions and are chemically and mineralogically similar to gabbros from the ocean floor. Whereas chemical analyses for transition zone and cumulate ultramafic rocks are not available in sufficient quantity to reconstruct the chemical nature of this lowest region of cumulate rocks, the relative proportions of minerals can be estimated from Vourinos⁷ and Quebec⁸ with the mineral chemistry from these sources supplemented by the data of Church and Riccio⁹ and England and Davis¹⁴. The total cumulate ultramafic and

transition zone rocks are estimated to be 60% olivine(Fo_{85}) + 30% clinopyroxene($\text{En}_{50}\text{Fs}_{7}\text{Wo}_{43}$) + 10% plagioclase(An_{80}). From these chemical constraints, the bulk composition of the oceanic crust is estimated in Table 1. (The MgO contents can be expected to vary locally, probably from ~16 to ~20% MgO, due to the variable histories and parameters of partial melting and melt extraction.) This very magnesian composition (~18% MgO) of the oceanic crust requires that the parental magma for ocean floor basalts be equally very magnesian.

Magma generation in the upper mantle

It is widely accepted that the massive residual harzburgites found at the base of many ophiolites are the result of partial melting and extraction of magma from the upper mantle^{15,16}. As such, these harzburgites must have been in equilibrium with the parental magma of ocean floor basalts and place important constraints on the chemistry of this parental magma.

Petrologically, the harzburgites have a relatively constant olivine to orthopyroxene ratio of 80:20 with trace amounts of spinel and clinopyroxene^{15,16}. The clinopyroxene in the harzburgite has exsolved from orthopyroxene during re-equilibration in the upper mantle or has crystallised from trapped interstitial melt which was not extracted from the upper mantle^{15,16}. As such, clinopyroxene was eliminated as a residual phase during the melting event in the upper mantle and the primary melt must have been in equilibrium with olivine(Fo_{91}) and orthopyroxene(En_{91}), as these are typical compositions of residual minerals in upper mantle harzburgites^{15,16}.

The residual harzburgites from several ophiolite and alpine peridotite terrains are remarkably similar in their modal proportions, mineral chemistry, and bulk compositions^{15,16}, indicating that the process of magma generation in ophiolites and the oceanic crust is relatively uniform, with melting continuing until the magma has $(\text{Mg}/\text{Mg} + \text{Fe}^{2+}) \sim 0.77$ and is multiply saturated with olivine and orthopyroxene as liquidus phases at the pressure of final equilibration, that is, 5–10 kbar.

Melting of lherzolite compositions must progress to high melt increments to eliminate clinopyroxene and spinel resulting in melt–solid equilibria involving only olivine, orthopyroxene, and a MgO-rich liquid. Mysen and Kushiro¹⁷ have shown that such melts contain 19.6% MgO, 9.7% FeO^* , and 49.6% SiO_2 at 20 kbar with 28.5% partial melting. Boettcher *et al.*¹⁸ have produced a similar liquid by melting a spinel lherzolite at 20 kbar in the presence of CO_2 and H_2O . Similarly, high-pressure melting experiments on peridotitic komatiites¹⁹ suggest that at 10 kbar pressure, liquids in equilibrium with olivine and orthopyroxene contain 18–19% MgO.

Table 1 Lithologies used to calculate the composition of the oceanic crust

	Average FAMOUS glass	Average oceanic tholeiite glass	Average Tortuga sheeted dyke	Average Tortuga 'gabbro'	Computed TZ ultramafic rocks	Calculated composition for oceanic crust

Can the fractionation of basalts (~10% MgO) generate the oceanic crust?

It is generally accepted that the pseudostratigraphy of oceanic crust is a consequence of igneous processes operating at mid-oceanic ridges. The major operating processes are magma intrusion and eruption at shallow crustal levels and gravitational crystal accumulation in large magma chambers at deeper crustal levels. Hence, a prerequisite of melt ascending from the mantle is that it be capable of reproducing the observed crustal lithologies and the cryptic variations within them. The basaltic glasses recovered in the FAMOUS area are among the most magnesian glass samples recovered from the ocean floor^{13,20}. Their high *mg* values (0.66–0.72) and high nickel contents (100–260 p.p.m.) led Langmuir *et al.*²⁰ to suggest that they represent primary partial melts of the upper mantle. If this interpretation is correct, then, with reference to the discussion above, fractional crystallisation of these basalts should be capable of generating the petrochemical characteristics of the oceanic crust as shown in Fig. 1.

If we use this ophiolite constrained petrological model (Fig. 1), one constraint placed on the primary magma is that it must be capable of fractionating 10% Fo_{90} (representing the cumulate dunites) followed by fractionation of cumulate pyroxene bearing and transition zone lithologies and still be capable of extruding an ocean floor basalt from the upper portions of the crustal level magma chamber. FAMOUS glass 527-1-1 is an example of a basalt proposed as a primary mantle melt^{20,21}. Extraction of

10% olivine (Fo_{90}) from a melt of this composition (Liq_1) produces a residual liquid (Liq_2) (Fig. 2). The daughter melt (Liq_2) has a very low MgO content and *mg* value and is incapable of fractionating further to give the remaining ultramafic and mafic cumulate sequence. Thus it is concluded that basaltic melts with 9–11% MgO are incapable of producing the observed crustal lithologies and cannot be the ultimate parent to more evolved ocean floor basalts. Additionally, the recent data of Bender *et al.*²² demonstrate that 527-1-1 has undergone at least 10% fractionation of olivine and that the composition of 527-1-1 has been modified to the extent that <2% (by weight) of olivine fractionation will mark the onset of plagioclase crystallisation.

The above discussion suggests that a substantially more magnesian liquid may satisfy the petrological constraints. Hence, a similar calculation has been performed for NT-23, an MgO-rich dyke from the Tortuga complex with the results tabulated in Fig. 2. In this case, the daughter liquid remains highly magnesian (MgO = 14%, *mg* = 72) after 10% olivine (Fo_{90}) removal. Cumulate pyroxenite and transition zone minerals indicate a further removal of about 20% of olivine, clinopyroxene, and plagioclase in the ratio 40:45:15 occurs. The residual liquid (Liq_3) still has a slightly higher MgO content than FAMOUS glass 527-1-1, but is close in composition to the latter. The observed crustal lithologies and cryptic chemical variations can be best modelled by fractionation of highly magnesian melt with ~18% MgO. During this process, residual liquids approach the composition of ocean floor tholeiites,

Fig. 2 Diagram demonstrating the results of fractional crystallisation of an ocean-floor tholeiite (FAMOUS glass) versus a high magnesian basalt (NT-23). The schematic columnar sections demonstrate that the FAMOUS glass is incapable of generating the petrological features of the oceanic crust, while fractionation of NT-23 is capable of reproducing these chemical features. See text for details.

including the most magnesian FAMOUS basalts, so that magmas erupted along mid-oceanic ridges are strongly evolved, secondary liquids which have been derived by almost 30% fractional crystallisation from the primary magma.

Flux of magma through the oceanic crust

Most models for the structure of oceanic crust at mid-oceanic ridges incorporate a large magma reservoir within the crust. Although direct evidence is lacking, thick cumulate sequences in ophiolites are ubiquitous and must represent the sites of former, volumetrically large magma chambers. These cumulate lithologies imply reservoirs ~5 km in vertical thickness situated just above the residual harzburgite, an estimate consistent with geophysical measurements¹⁰. The width of sea floor over which eruptions occur reflects a reasonable value for the width of the magma chamber. Measurements are scarce, but in the FAMOUS area basalts were erupted over the entire 6 km width of the median valley¹³. Therefore, a magma reservoir beneath an active ridge may have a volume of about 30 km³ (3×10^{10} m³) per km of ridge length.

If the magma chamber maintains a steady state, the volumetric addition of melt to the magma reservoir from the mantle is the product of spreading rate (~2 cm yr⁻¹) and crustal thickness (7 km), that is 1.4×10^5 m³ per yr per km of ridge length. This volume is balanced by the extrusion of $\sim 0.4 \times 10^6$ m³ yr⁻¹ of magma from the top of the reservoir per km of ridge length. However, the important consideration is that the flux of magma into and out of the magma reservoir is extremely small compared with the volume of the reservoir. (Nisbet and Fowler²³ have reinterpreted the data from the FAMOUS area to exclude any volumetrically large magma chamber from operating in the area at present. However, even if the estimate presented here is two orders of magnitude too high, the conclusions presented here remain the same.) Consequently, the addition of melt from the mantle has no measurable effect on the overall chemistry of the magma chamber. Any variation in the composition of mantle-derived melts entering the chamber will also be undetectable and it seems highly unlikely that such variations could be observed in surface eruptions. More likely, the compositional variations observed in erupted basalts²⁰ reflect fractional crystallisation and magma mixing within the crustal magma reservoir and are the result of crustal processes rather than dynamic mantle melting.

However, highly magnesian, aphyric lavas have been described from Baffin Island^{24,25} and Svartenhuk^{24,25}, and have recently been discovered as dykes in the Tortuga ophiolite

complex, Chile²⁶, indicating that occasionally such primary melts do reach the near-surface environment. As it seems unlikely that such magmas can ascend uninterrupted once a steady-state magma chamber has developed they must erupt before the reservoir development or in the dying stages of activity when the reservoir has largely solidified. The former situation may arise during the earliest stages of continental rifting and would fit the tectonic position of the Baffin Bay lavas²⁴. The latter situation may be the instance for the Tortuga dykes.

High magnesia dykes from Tortuga

Table 2 shows the compositions of four MgO-rich dykes which intrude the cumulate rocks in the Tortuga ophiolite complex. Textural and petrological evidence indicates that these dykes were intruded as liquids²⁶. The similarity of NT-23 to the Group II olivine basalts of Baffin Island and Svartenhuk²⁴ as well as the average oceanic crust (Table 1) indicates that this is a primary mantle melt and the parental magma for ocean floor basalts.

In conjunction with the data and observations of Donaldson and Brown²⁷ and Rhodes and Dungan²⁸, it is critical to evaluate the role of high calcium picritic magmas in the fractionation scheme producing ocean floor basalts. The similarities of NM-5 with Donaldson and Brown's²⁷ melt inclusions and Rhodes and Dungan's²⁸ calculated parental magma is surprising in view of the diverse methods from which these values have been derived. The gradual build-up of calcium in the magma during fractional crystallisation of the primary melt culminates in high calcium picritic liquids with ~12–14% MgO. Thus, a liquid line of descent from primary mantle melts (18% MgO) through high-calcium picrites (for example, NM-5) towards oceanic tholeiites is indicated by the compositions of these Tortuga dykes.

Conclusions

The present discussion has demonstrated the significance of highly magnesian basalts in the formation of the oceanic crust. Correlatively, ocean-floor tholeiites (9–11% MgO) cannot be accepted as primary mantle melts. High-temperature crystallisation experiments clearly indicate that oceanic tholeiites are multiply saturated with combinations of plagioclase, olivine, and clinopyroxene at low pressures^{2,3} as a consequence of low pressure fractionation. O'Hara^{2,3} has repeatedly used this powerful argument against the primary nature of oceanic tholeiites.

As a result of the steady-state magma chamber operating in the oceanic crust, O'Hara²⁹ conceptualised several characteristics of magmas in the oceanic crust which are controlled and modified by the magma chamber itself. Consequently, there remains a distinctive compositional gap between the magma segregating from the upper mantle and oceanic tholeiites with 9–11% MgO. Because this gap represents the effects of extensive fractional crystallisation and magma mixing, caution must be exercised when evaluating mantle chemistry and processes using evolved compositions.

I thank W. I. Ridley, R. K. O'Nions, J. Casey, J. Karson, C. Stern, M. Dobbs, and L. Oviedo for comments and assistance in the field. I thank L. Oviedo and E. Godoy of Santiago, Chile for their hospitality. This work is supported by NSF grants EAR 76-82456 and DPP 74-21415.

Note the gradual increase in calcium in the magma during fractionation of the primary melt (NT-23) resulting in high calcium picrites similar to the estimates of the parental magma for ocean floor tholeiites by Donaldson and Brown²⁷ and Rhodes and Dungan²⁸. All of the Tortuga samples are fine to very fine grain and have been altered to variable extents. Cpx (~En₄₄Di₄₂Pl₁₄), Plag (~An₇₀) ilmenite, and Picotite (Al₂O₃ = 30–40%, FeO = 24–26%, Fe₂O₃ = 1–2%, Cr₂O₃ = 23–31%, MgO = 4–9%) are observed in subophitic to interstitial textures. NT-23 contains a few per cent of plagioclase megacrysts.

* Most magnesian dyke reported by Stern³⁰.

Palaeoclimatic inferences from former glaciers in Scotland and the Lake District

J. B. Sissons

Department of Geography, University of Edinburgh, High School Yards, Edinburgh, UK

Firm line altitudes of Loch Lomond Advance glaciers in Scotland and the Lake District imply that snowfall was associated mainly with south to southeasterly air streams preceding fronts. Precipitation was high in the south-west Grampians and very low in the north-west Cairngorms and Speyside. The junction of polar and relatively warm ocean waters at the latitude of south-west Ireland was associated with many depressions following more southerly tracks than at present. It is suggested that during ice-sheet growth the zone of maximum snowfall moved southwards over the British Isles.

THE last ice-sheet that existed in the British Isles is generally believed to have attained its greatest extent ~17,000 BP, when its southern margin was located in the north-west Midlands. Radiocarbon dating of the basal organic material in present or former lake sites shows, if the dates are valid, that extensive areas of the Scottish Highlands had become ice-free by ~13,000 BP¹. By this time the polar water that had surrounded the British Isles had been replaced by much warmer water². This suggests that the remains of the ice-sheet would have melted rapidly, the British Isles becoming ice-free probably between 13,000 and 12,500 yr BP.

However, the polar waters subsequently spread southwards again, extending as far as the latitude of south-west Ireland³. This was accompanied by a return to cold conditions. This cold period—the Loch Lomond Stadial (equivalent to the Younger Dryas of Scandinavia)—occurred around 11,000–10,000 yr BP (more exact dating is being discussed). This paper makes climatic inferences from the glaciers that developed at this time.

Scotland

Figure 1 shows the limit of the Loch Lomond Advance in Scotland, although evidence is lacking in some areas, most notably in parts of the western Highlands, where a broken line is shown. Figure 2 shows generalised equilibrium firm lines for the former glaciers in the Highlands and Inner Hebrides based on 226 data points. Firm lines were calculated from altitude/area distributions of the glacier surfaces, using a method described elsewhere⁴.

By far the largest mass of ice was in the western Highlands southwards from the latitude of Skye (Fig. 1). This seems to suggest that snowfall was associated mainly with air streams from the west or south-west. However, superimposed on this pattern is another one: this is the contrast between north- and south-facing glaciers in many individual upland areas. For

example, on the external slopes of the Cuillin Hills of Skye (A in Figs 1 and 2) there is a continuous line of cirques facing directions that change from south-southwest through west to north-east. One might expect, from the influence of direct insolation, north-facing glaciers to have been larger and to have extended to lower altitudes than south-facing ones. However, the converse applied: the combined volume of the two glaciers that faced north and north-east was only one-third of that of the two glaciers that faced south-southwest, and the former had firm lines 300 m higher than the latter⁵.

In the central Grampians on the high ground on both sides of the Pass of Drumochter (through which run the Perth-Inverness railway and main road (A9)) ice built up to form an ice-cap, whose outlet glaciers flowed into the pass and down many other valleys (B in Figs 1, and 2). The ice-cap was asymmetrical in form, the bulk of it lying south of the east-west axis of the high ground. Equilibrium firm lines rose northwards, from below 700 m on the southernmost parts of the ice-cap to 800 m or more on its northern parts.

In the western Cairngorms (C in Figs 1 and 2) the largest glacier flowed southwards. In contrast, in the northern part of the area only three north-facing cirques contained glaciers, all of which were very small. Firm lines rose from below 800 m in the south to over 1,000 m in the north⁶.

The regional firm line in north-west Scotland increased in altitude from the coast to the interior (Fig. 2). This overall trend masks the detailed pattern in some individual upland areas. For example, in the Ben More Assynt Range, in the Fannich mountains, and in the mountain mass culminating in Ben Dearg, southward-flowing glaciers were larger, sometimes very much larger, than those that faced northwards⁷.

All the specific areas mentioned above have a north-south extent of no more than 25 km. Hence regional temperature differences cannot be invoked to explain the north-south contrasts. In fact, temperature differences related to altitude would have favoured the higher, north-facing glaciers in that here a higher proportion of the annual precipitation would have fallen as snow. Furthermore, the influence of direct insolation opposes the pattern described above. Hence some major factor must have been over-riding these influences. I suggest the only possible explanation is much higher precipitation on the southern sides of individual upland areas than on their northern sides. This in turn implies that the principal snow-bearing air streams were from southerly directions.

The firm lines in the south-east part of the Grampian Highlands, corrected for the influence of direct insolation (unpublished data), trend almost exactly parallel with the Highland Fault, rising northwestwards from 500 m to over 800 m (D in Fig. 2). Along the fault there is an abrupt increase of

Fig. 1 Limit of the Loch Lomond Advance in Scotland. The map includes unpublished information provided by C. K. Ballantyne, R. Cornish, M. Robinson, D. G. Sutherland, P. Thorpe and T. Wain-Hobson. For reference letters see text.

several hundred metres in ground altitude. The firn lines imply that, at any given altitude, snowfall was heaviest along the Highland Edge and diminished thence northwards into the interior of the Highlands. This indicates uplift of air streams as they crossed the Highland Edge. Such uplift could not have occurred with southwesterly air streams, for they would have flowed parallel with the Highland Edge: with snow-bearing winds from southerly directions, it must have been south to southeasterly air streams that brought the principal snowfalls to the south-east Grampians.

Lake District

The Lake District differs from the preceding examples in that there is no south to north rise in firn line altitudes (unpublished data). In fact there is no significant trend in any direction. A major factor here was snow transfer to glaciers from surrounding higher ground by wind. Potential snow-blowing areas were measured on Ordnance Survey maps for each glacier and each quadrant, using rules specified elsewhere⁸. Each snow-blowing area was divided by its associated glacier area to give a snow-blowing ratio. Regression of firn line altitudes on snow-blowing ratios for the north-west quadrant for all glaciers indicated no significant relationship. This applied also to the north-east quadrant. For the south-west and south-east quadrants, however, there are highly significant inverse relationships. Thus some glaciers were relatively low because of snow blown from

the two latter directions and this distorts the distributional pattern of firn line altitudes.

Snow-blowing would have been most important during and immediately after snowfall, so that the above relationships again point to the importance of snowfall with southerly winds. The synoptic situation implied is one in which warm or occluded fronts approached from the west or south-west, the major snowfalls occurring with south to southeasterly winds before fronts arrived, succeeded by further snowfalls with moist south to southwesterly air streams after fronts had passed. Frequent repetition of this situation necessitates many depressions following more southerly tracks than are normal at the present day, this in turn being related to the junction of polar and relatively warm ocean waters at the latitude of south-west Ireland.

The largest glaciers in the Lake District were along the east-west mountain axis, especially in the central mountain area. This reflects the strong influence of relief on precipitation, as at present. However, despite much high ground, glaciers were very small in the north-west (north and north-east of Ennerdale): and size alone exaggerates their importance, for all of them occupied locations relatively sheltered from direct insolation and many have high snow-blowing ratios for the south-east and/or south-west quadrants. This implies relatively low precipitation in the north-west Lake District and points to southerly air streams, especially south to southeasterly ones, as having been associated with the principal snowfalls, the north-west being in the precipitation shadow of the central mountain area.

Snowfalls and glacier growth

Although south to southeasterly air streams were associated with the major snowfalls in the Highlands, moist southwesterly air streams would have been increasingly important providers of

Fig. 2 Equilibrium firn line altitudes for Loch Lomond Advance glaciers in the Highlands and Inner Hebrides. Altitudes in hundreds of metres. For reference letters see text.

precipitation towards the west. Hence the largest ice mass developed in the west (favoured also by relief) and the regional firn line was lowest (300 m) in the south-west Grampians, which was most exposed to air streams from both directions. Present precipitation in the former glacier accumulation areas of the south-west Grampians is 3,000–4,000 mm. In stadial times it would have tended to be less due to lower air temperatures, but more due to the much more vigorous interaction of air masses⁸. Assuming these two tendencies roughly cancelled each other, we may obtain an indication of former summer temperatures using Liestøl's graph (Fig. 3). Allowing for 20–25% summer rain, this graph indicates that with a summer temperature of $3.5 \pm 0.5^\circ\text{C}$ the range of annual precipitation covered is 2,700–4,000 mm. I suggest this considerable range includes all reasonable possibilities. Using the 400 m firn line this is equivalent to a temperature at sea level (May–September) of 6.0°C , or a July temperature of 7.5°C . As these temperatures are derived from firn lines for glaciers in equilibrium, temperatures during the stadial would have been slightly lower.

In the Grampians the firn line rose 700 m (Fig. 2). That this rise was due mainly to precipitation differences rather than to temperature differences is indicated by the great contrasts in glacier dimensions. For example, in the south-west Grampians the Loch Lomond glacier alone had a volume of about 80 km^3 , whereas the combined volume of the 17 glaciers that existed in the Cairngorms, despite much higher altitudes, was only 1.7 km^3 . The glaciers in the north-facing cirques of the north-west Cairngorms were tiny and four cirques at 1,000 m altitude failed to nourish glaciers, suggesting extremely low precipitation here. An indication of the amount may be obtained as follows.

Assuming 750 yr for glacier growth, the average annual net accumulation on the Loch Lomond glacier above the equilibrium line was slightly over 600 mm (water equivalent). For the three north-facing Cairngorm glaciers the values are 100–150 mm. This suggests that precipitation on the Loch Lomond glacier was 4–6 times that of the three Cairngorm ones. Even taking the maximal value of 4,000 mm annual precipitation for the south-west Grampians proposed above, this implies only about 800 mm in the north-west Cairngorms. However, even this low value seems to be too high, for the following reasons. (1) During much of the time it was advancing the Loch Lomond glacier would have been subject to loss through calving in the ablation season. (2) This glacier flowed southwards whereas the three Cairngorm glaciers flowed northwards. (3) The latter were backed by plateaus from which snow would have been blown onto them by southerly winds. (4) The above estimate includes an allowance of 20–25% for summer rain, which seems reasonable for the south-west Grampians but is almost certainly too high for the high-altitude glaciers of the north-west Cairngorms. Taking these four factors into account, I suggest that annual precipitation at an altitude of 1,000 m in the north-west Cairngorms may well have been only 500–600 mm. At the much lower altitude of the floor of the Spey Valley 200–300 mm seems a reasonable estimate. Birks and Mathewes⁹ concluded from pollen analyses that the Spey Valley had "a rather arid climate" during the Loch Lomond Stadial.

Figure 1 also shows the very small area covered by glaciers in north-west Scotland. This partly reflects the much smaller area of high ground compared with further south in the Highlands. This is not apparently the sole cause, however. The average firn line altitude for 68 glaciers in north-west Scotland is 520 m. For 64 glaciers in the Lake District it is 540 m. As these two areas differ in latitude by 400 km, one might reasonably expect a much lower average firn line in north-west Scotland due to the influence of temperature. The small difference therefore suggests that precipitation was considerably lower in north-west Scotland than in the Lake District. The former probably received much of its precipitation from occasional depressions whose centres normally passed to the north-west of the area as they tracked northeastwards. But the majority of depressions took more southerly tracks (related to the junction of cold and relatively warm ocean waters) and this seems to have been the

basic cause of the precipitation deficiency in north-west Scotland.

Ice-sheet accumulation

This interpretation seems relevant to ice-sheet accumulation. It is known that when the last ice-sheet existed, the Southern Uplands of Scotland were a major centre of ice accumulation. In the west the Southern Uplands ice at first flowed northwards, despite the opposition of Highland ice, before the latter deflected it. The Southern Uplands ice extended nearly to the site of Edinburgh and it produced the major assemblage of ice-moulded features in the Tweed basin. However, during the Loch Lomond Stadial there were only paltry glaciers in the Southern Uplands. Some of these glaciers are not shown in Fig. 1 because details are not available, but the mapping is complete in the west (Loch Doon Basin and vicinity), which had previously been a major centre of ice-sheet radiation.

The question thus arises: why were ice-sheet conditions so different from those in the Loch Lomond Stadial? A lower firn line during ice-sheet build-up than during the stadial would have allowed glaciers to accumulate more widely in the Southern Uplands. However, a lower firn line would also have benefited the Highland ice. If we regard Fig. 1 as portraying a stage in ice-sheet growth, the lowering of the firn line would probably have caused the Highland ice to overwhelm the Southern Uplands before they could develop a large ice mass.

Fig. 3 The relationship between accumulation (winter balance) and summer temperature at the firn line for certain Norwegian glaciers. Compiled by O. Liestøl.

Conclusions

As the oceanic polar front moved southwards during ice-sheet growth, and with it the polar front in the atmosphere, I suggest that the zone of maximum precipitation also moved southwards. During the Loch Lomond Stadial, precipitation seems to have been deficient in the northern mainland of Scotland. We may envisage the next stage as a decrease in precipitation over the main Highland ice mass and an increase over the Southern Uplands. This idea can also explain why the Lake District, with only 3.3 km^3 of ice during the Loch Lomond Stadial, was an important centre of ice radiation in ice-sheet conditions. Continued southwards movement of the zone of maximum precipitation can explain why the Welsh uplands, where stadial glaciers were tiny, had an extensive plateau ice-cap feeding into the ice-sheet.

If this idea is valid one consequence is as follows: Many maps of the glaciation of the British Isles have shown ice from the Scottish Highlands flowing down the Firth of Clyde and through the Irish Sea to reach south-west Wales and the English Midlands. Among the erratics that contribute to this picture are

the famous ones of Ailsa Craig. However, if the zone of maximum precipitation moved southwards as an ice-sheet built up, thus affecting the relative importance of different parts of the ice-sheet, one may envisage erratics having been transferred from one area of local ice dominance to the next, without the occurrence of the continuous flow apparently suggested by erratics.

I thank Dr O. Liestøl for permission to include Fig. 3, and also Mrs M. Dale for comments.

Transmission of allosteric effects in DNA

M. Hogan, N. Dattagupta & D. M. Crothers

Department of Chemistry, Yale University, New Haven, Connecticut 06520

Binding of distamycin induces a cooperative transition of calf thymus DNA to a new form with higher affinity for the drug and altered structural properties.

A PROTEIN or other ligand bound to one section of DNA can affect the expression of genetic information in a different DNA segment by two general mechanisms. The first of these is direct physical interaction between one bound protein and another. For example, promoter and repressor binding sites may overlap, as in the *Escherichia coli lac* operon¹, so that binding of repressor interferes sterically with polymerase binding, producing negative control. Positive control by direct interaction could result from favourable contacts between polymerase and a bound activator.

The alternative possibility for exertion of control-at-a-distance is indirect influence of one bound protein on binding of another because of structural alteration of the DNA that intervenes between the two sites. We refer to this as transmission of allosteric effects through DNA, a mechanism which though purely conjectural is supported by enough indirect evidence to require its serious consideration. For example, two arabinose promoters whose polymerase binding sites are separated by 100 base pairs clearly interact². At the level of model studies the size of the DNA region excluded by binding of drugs such as actinomycin³ or ethidium⁴ is larger than the size of the drug molecule as measured along the helix axis. Therefore, the neighbour exclusion effect⁵ must be propagated through the DNA helix; a specific stereochemical mechanism has been proposed by Sobell *et al.*⁶. The clearest example of transmission of long-range allosteric effects in a polynucleotide is the demonstration by Pohl *et al.*⁷ that ethidium binding affects the balance between the high and low salt double-helical forms of poly d(GC). Drug binding at high salt concentration was markedly cooperative, implying interaction over hundreds of base pairs. Furthermore, Wells *et al.*^{8,9} have provided evidence for transmission of structural effects along DNA.

Our purpose here is to show that a naturally occurring drug, distamycin, alters cooperatively the properties of a natural double-helical DNA. The results are interpreted as an allosteric conversion of DNA to a form that exhibits increased distamycin binding, and imply that a length of hundreds of base pairs of the average DNA is altered by drug binding.

Cooperative binding of distamycin to calf thymus DNA

Distamycin is a basic oligopeptide which exhibits strong binding to DNA¹⁰. The interaction is only weakly ionic¹¹ and does not involve intercalation¹²; attachment probably occurs in the small groove^{12–14}. Circular dichroic spectral changes imply a substan-

tial DNA conformational change^{11,15}; viscosity measurements reveal a length increase and perhaps an increase in persistence length¹⁶. Binding occurs preferentially to AT-rich regions^{16,17}.

We used a phase partition technique to measure the equilibrium binding of distamycin to calf thymus and *E. coli* DNA. This method was chosen because aqueous solutions of distamycin are too unstable to allow equilibrium dialysis, and optical titrations require the questionable assumption of a linear relationship between optical change and extent of binding. Figure 1 shows the marked contrast in binding properties observed for the two DNA samples. Cooperative binding of distamycin to calf thymus DNA is indicated by the pronounced maximum which occurs at about one drug molecule bound per 30 base pairs. Much weaker binding (except in the limit as the extent of binding approaches zero) characterises *E. coli* DNA, the monotonically decreasing curve indicating that cooperative interactions are absent. A cooperative binding isotherm was also found for distamycin with calf thymus DNA in 1 M salt concentration (data not shown).

DNA length changes on binding

We used the method of transient electric dichroism of rod-like DNA molecules¹⁸ to measure apparent length changes that occur in DNA on distamycin binding. Figure 2a and d show such data for calf thymus and *E. coli* DNAs, again revealing a distinct difference between the two samples. The apparent length of calf thymus DNA molecules increases by about 13% at a ratio of one drug molecule bound per 30 base pairs, and decreases again as more distamycin is added. At the maximum of the curve the calculated length increase is about 14 Å per drug molecule, much greater than we observed for intercalating drugs (2–4 Å) by the same technique¹⁹. *E. coli* DNA, on the other hand, showed no detectable length increase in the same conditions (Fig. 2d). Other DNA samples, such as those from *Clostridium perfringens*, *Micrococcus luteus* or human placenta changed in length by only a few per cent (data not shown) without evidence for the local maximum observed for calf thymus DNA. The antibiotic netropsin produced length changes in *E. coli* and calf thymus DNAs closely similar to those found for distamycin (manuscript in preparation).

Ethidium as a probe of altered DNA structure

To obtain further evidence for an alteration of DNA structure by distamycin, we studied ethidium binding in the presence of distamycin. We found a striking change in the orientation of the bound ethidium chromophore (at $r_{\text{ethidium}} = 0.1$) in the presence of distamycin at $r_{\text{distamycin}} = 0.03$ (this r value corresponds to the maxima of both the distamycin binding isotherm and the distamycin-induced length increase).

The reduced dichroism, ρ , of a molecule orientated in an electric field is given by $\rho = \frac{1}{2}(3 \cos^2 \alpha - 1)\Phi$, where α is the angle between the transition moment and the orientation direction, and Φ is the fractional orientation of the sample^{20,21}. In the limit of infinite electric field, Φ approaches 1, and α can be calculated from the extrapolated value of ρ , ρ_∞ . The maximum negative dichroism occurs when $\alpha = 90^\circ$, yielding $\rho_\infty = -\frac{1}{2}$. Figure 3 shows the field dependence of the reduced dichroism of bound ethidium in the presence of distamycin at $r_{\text{distamycin}} = 0.03$. The much larger dichroism values observed in the presence of distamycin extrapolate to -1.5 , indicating that the ethidium chromophore is perpendicular to the helix axis. In the absence of distamycin, as we have reported¹⁹, the ethidium dichroism is considerably smaller, implying tilting of the intercalated chromophore out of the plane perpendicular to the helix axis.

Fig. 1 Scatchard plot²⁴ of the binding equilibria of calf thymus (a) and *E. coli* (b) DNAs with distamycin at 11°C in PES buffer (50 mM NaCl, 6 mM Na₂HPO₄, 2 mM NaH₂PO₄, 1 mM EDTA, pH 6.5). Duplicate calf thymus (●, ○, □, △) and *E. coli* (◆, ◇) DNA samples were prepared by dissolving commercial (Sigma) DNA sample in 6 mM Na₂HPO₄, 2 mM NaH₂PO₄, 1 mM EDTA, 1 mM Na cacodylate buffer and sonicating for 30 min at ice bath temperature with a Branson sonicator operated at full power. Following deproteinisation by repeated phenol extraction, samples were dialysed into 8 mM Na₂HPO₄, 2 mM NaH₂PO₄, 180 mM NaCl, 1 mM EDTA and fractionated on a Sepharose 4B column. The centre portion of the elution profile was pooled and dialysed into measurement buffer. Transient electric dichroism¹⁸ and gel electrophoresis against markers of *Hae*III restriction fragments of ColEI DNA²⁵ yielded 150 base pairs as the size of the calf thymus and *E. coli* samples used for measurement. Binding isotherms were measured by partitioning the drug between *n*-pentanol and an aqueous solution of DNA. 2 ml of *n*-pentanol was added to 2 ml of PES buffer containing DNA and distamycin A (Boehringer, Sigma, purified by LH 20 (Pharmacia) chromatography in CH₃OH/CHCl₃, 9/1 volume ratio) at known total concentrations. The mixture was shaken at 11°C for 2 h, and the phases were allowed to separate. The free distamycin concentration (m) was determined from the absorbance of the organic phase ($\epsilon_{306} = 42,400 \text{ M}^{-1} \text{ cm}^{-1}$), using the partition coefficient $K = 19.5$ (organic/aqueous) determined in the absence of DNA. The total distamycin concentration (free+bound) was measured by dissociating the aqueous complex through addition of an equal volume of dimethyl sulphoxide (DMSO) (ϵ_{306} in PES/DMSO, 1:1 volume ratio = $32,800 \text{ M}^{-1} \text{ cm}^{-1}$). The bound drug concentration was calculated from the difference of free and total concentrations, and divided by the DNA base pair concentration to obtain r , the number of drug molecules bound per base pair. The solid curve (a) was calculated from a statistical mechanical theory (see text) of cooperative allosteric transition of calf thymus DNA from its initial form to another structure that has higher affinity for distamycin (manuscript in preparation).

Figure 2b, c, e, f show the results obtained from experiments similar to that in Fig. 3 but at different $r_{\text{distamycin}}$ values ($r_{\text{ethidium}} = 0.1$). The ethidium orientation angle (b) reaches a maximum at nearly the same $r_{\text{distamycin}}$ value for which the length increase is maximal. The calf thymus DNA length increase due to distamycin in the presence of constant ethidium (c) is only slightly smaller than observed in absence of ethidium (a). The control sample of *E. coli* DNA showed no variation in length or ethidium orientation angle as a function of distamycin concentration (e, f). The dichroism, ρ_∞ , of ethidium bound to *E. coli* DNA was very similar to the value found for ethidium bound to calf thymus DNA in the absence of distamycin.

Fig. 2 Apparent fractional length (L) changes (a, c, d, f) and ethidium orientation angle (α) changes (b, e) as a function of degree of distamycin binding for calf thymus (a, b, c) and *E. coli* (d, e, f) DNA samples, prepared as described in the legend to Fig. 1 and dissolved in dichroism buffer (0.5 mM Na₂HPO₄, 1 mM NaH₂PO₄, 0.25 mM Na₂EDTA, pH 7.0) at 11°C. Additional samples of calf thymus DNA were obtained by protease K (Merck) digestion and phenol extraction of mononucleosomes isolated from HI-depleted chromatin²⁶. These samples gave results identical to those obtained with sonicated samples. Samples a and d contain no ethidium, whereas samples b, c, e and f contain a constant amount of bound ethidium, $r_{\text{ethidium}} = 0.1$. Lengths were calculated from the dichroism rise time τ and Broerema's equation²⁷ for the rotational diffusion constant of a cylinder, which we earlier verified for rod-like DNA molecules¹⁸. We assumed no change in helix diameter on drug binding, an assumption justified by the logarithmic dependence of r on diameter, compared with variation with the third power of helix length. Length values are normalised to 1 at zero distamycin concentration. Ethidium orientation angles were measured at 520 nm by extrapolation of the dichroism to infinite field as described in the text. a (●), Length change for calf thymus DNA in absence of ethidium; b (○), angle change for calf thymus DNA in presence of ethidium; c (×), length change for calf thymus DNA in presence of ethidium; d (△), length change of *E. coli* DNA without ethidium; e (□), length change of *E. coli* DNA with ethidium; f (■), angle change of *E. coli* DNA with ethidium present.

We also investigated the dichroism of ethidium at constant $r_{\text{distamycin}} = 0.03$ and varying r_{ethidium} values (Fig. 4). Up to about $r_{\text{ethidium}} = 0.1$, the dichroism extrapolated to infinite field was equal to -1.5 , but larger r_{ethidium} values led to a progressive decrease in the dichroism.

Finally, we examined the influence of bound distamycin ($r_{\text{distamycin}} = 0.03$) on the binding isotherm of ethidium, and

observed that ethidium binding becomes cooperative. We were not able to use the partition technique at the low salt concentrations used for Fig. 1, because the ethidium partition coefficient was concentration dependent in those conditions. Therefore, the data shown in Fig. 5 were measured at 1 M salt concentration. However, we verified that the distamycin-calf thymus DNA binding isotherm was cooperative in these salt conditions, with the distamycin binding affinity estimated from r/m at its peak reduced by about threefold from the value in Fig. 1. As seen in Fig. 5, r_{ethidium} values less than about 0.06 are characterised by lower r/m values than found in the absence of distamycin (open circles). Therefore, distamycin at $r_{\text{distamycin}} = 0.03$ substantially reduces the affinity of calf thymus DNA for ethidium, in the limit as r_{ethidium} approaches zero.

Interpretation as an allosteric transition of DNA

There are two general mechanisms which can lead to cooperative binding of drugs to nucleic acids, as found in Fig. 1; (1) the drugs can interact directly on the DNA lattice, as, for example, in the stacking of acridines on the DNA helix, or (2) the drug molecules can interact indirectly by altering the state of the nucleic acid. Examples of the latter are the ethidium-induced transformation of poly d(GC) from one form to another⁷, and conversion of poly dA·2poly rU from triple to double helix²². Mechanism (2) requires that the drug bind more tightly to the alternative form; for example, ethidium binds more tightly to double-helical poly dA·poly rU than to triple-helical poly dA·2poly rU. The process is analogous to allosteric conversion of a protein from a low to a high affinity form by an effector molecule.

Our results strongly support alternative (2), namely, that distamycin serves as an allosteric effector to convert calf thymus DNA from one form to another. The results with the ethidium probe are essential for this conclusion. The distamycin molecule is long enough to cover only about five DNA base pairs. Therefore, at $r_{\text{distamycin}} = 0.03$ only about 15% of the base pairs could be in contact with distamycin, leaving about 85% of the DNA molecule free. Thus, if the only effect were clustering of distamycin molecules, 85% of the DNA should show unaltered ethidium binding properties. However, the measured ethidium dichroism can reach the theoretical limiting value of -1.5 (Fig. 3) only if virtually all the ethidium molecules are bound perpendicular to the helix axis. Therefore, the 85% of the DNA that is distamycin-free cannot be binding ethidium in the same way as in the absence of distamycin, and we conclude that bound

Fig. 3 Extrapolation of the observed dichroism of ethidium ($r_{\text{ethidium}} = 0.1$) to infinite field in the absence (a) and presence (b) of distamycin, $r_{\text{distamycin}} = 0.03$. Calf thymus DNA samples, dissolved in dichroism buffer, 11 °C.

Fig. 4 Variation with extent of ethidium (E3) binding of the extrapolated dichroism of ethidium bound to calf thymus DNA in the presence of distamycin, $r_{\text{distamycin}} = 0.03$. Dichroism buffer, 11 °C.

distamycin alters the form of virtually all the DNA. This conclusion is also supported by the ethidium binding isotherm (Fig. 5), as distamycin at $r_{\text{distamycin}} = 0.03$ reduces the affinity for ethidium by at least a factor of two in the limit as r_{ethidium} approaches zero. This would not be possible if 85% of the DNA were unaltered in structure and ethidium affinity.

Comparison with theory

To determine quantitative features of the observed allosteric transition, we developed a general statistical mechanical theory of the process (manuscript in preparation). The model allows the DNA double helix to be in one of two forms: form (1) has a lower affinity for distamycin than form (2), but (1) has slightly lower free energy in the absence of distamycin and so is generally the

Fig. 5 Binding isotherm of ethidium to calf thymus in absence (O) and presence (●) of distamycin, $r_{\text{distamycin}} = 0.03$ r and m were measured by the phase partition technique as described in the legend to Fig. 1, except that samples were dissolved in PES buffer made up to a total concentration of 1 M in NaCl

preferred structure. A positive interfacial free energy characterises each boundary between forms (1) and (2). Figure 1 shows a comparison of the experimental binding isotherm with a theoretical curve obtained by adjusting the parameters of the theory for best fit. The calculation reveals that the rising portion of the binding isotherm is associated with the cooperative conversion of the double helix from form (1) to (2). After the

maximum is reached, the transition is essentially complete and the curve follows the binding isotherm expected for pure form (2). The intrinsic distamycin binding constants⁵ are $0.3 \times 10^6 \text{ M}^{-1}$ for form (1) and $4.8 \times 10^6 \text{ M}^{-1}$ for form (2). A neighbour exclusion range⁵ of six was assumed for form (2) so as to fit the data beyond the maximum in r/m ; a more accurate theory would have to take account of the (unknown) base sequence preference of distamycin when binding to form (2) (ref. 5). The interfacial free energy necessary for the observed cooperative transition is 3–4 kcal mol⁻¹. Only a very small free energy difference, about 0.02 kcal per mol of base pairs, is found between forms (1) and (2). However, because of the cooperative character of the transition, less than 1% of form (2) is present in the absence of distamycin.

An important result of the calculation is that the average length of form (1) and form (2) helices is hundreds of base pairs in the transition region. This conclusion has two significant implications: first, allosteric effects in DNA can be transmitted over hundreds of base pairs, and, second the theory is only approximately applicable to the measurements, as the latter were done with DNA fragments about 150 base pairs long.

Characteristics of the altered form

Thus, three features of the DNA structure induced in calf thymus DNA by distamycin binding are (1) ethidium binds to form (2) with the long wavelength transition perpendicular to the DNA helix axis; (2) the apparent length of form (2) is substantially larger than that of form (1), by at least 13%, which

is the apparent length increase at the point where the cooperative transition to form (2) is essentially complete; (3) form (2) becomes distinctly shorter in apparent length as more distamycin is bound.

Why only calf thymus DNA?

Perhaps the most surprising feature of our results is the failure to obtain the effect with any DNA except that from calf thymus, out of three bacterial and two mammalian DNA tested. We believe that this is due to the requirement for near-equality of the free energies of the two forms, and the sensitivity of this free-energy balance to the details of base sequence or base modification, or both. If the average free energy difference of 20 cal per mol of base pairs estimated between forms (1) and (2) in calf thymus DNA were increased to 200 cal per mol of base pairs (a change per base pair considerably less than the thermal energy), the transition would not be observed. Hence, we conclude that the details of DNA base modification and sequence are extremely important for the long-range transmission of allosteric effects. Thus, negative results found in particular cases cannot be taken as general evidence against propagation of structural effects along DNA²³. The finding that distamycin acts as effector of an allosteric conversion in calf thymus DNA, when considered with previous evidence⁷⁻⁹, shows that DNA can transmit structural influences. It remains to be seen, however, whether such phenomena are of general importance in genetic regulation.

Construction of a site-specific, deletion-frameshift mutation in an essential gene of bacteriophage ΦX174

M. Zafri Humayun & Robert W. Chambers

New York University School of Medicine, Department of Biochemistry, 550 First Avenue, New York, New York 10016

By in vitro methods, we have deleted 80 nucleotides from a preselected site in the coding sequence of gene G of bacteriophage ΦX174. This mutant (GV/FS ZH1) also carries a –2 frameshift. The mutation is lethal, but mutant virus can be stably maintained on host strains bearing plasmids carrying ΦX gene G.

To explore molecular mechanisms of mutation by carcinogens, we have developed a system for examining the *in vivo* expression of well characterised, site-specific, covalent modifications of biologically active DNA^{1,2}. Because of the extensive chemical and biological information available^{3–5}, we have chosen an

essential gene (gene G) of the virulent phage, ΦX174, for our initial studies. As the nature of the mutation produced by a site-specific modification cannot be predicted, we need a host that is permissive for all types of mutation in gene G. To deal with this problem in the most general way, we have developed cell lines that carry ΦX gene G on a plasmid¹. These pΦXG-bearing hosts produce functional ΦX gene G protein and provide a means of rescuing ΦX174 carrying mutations in this gene.

We have demonstrated that cells carrying pΦXG are permissive for conditionally lethal mutants (both nonsense and missense) in gene G (refs 1, 2 and R.W.C., unpublished results). A crucial test of our system is to show that pΦXG-bearing host cells are also permissive for lethal mutations in gene G (frameshifts, large deletions and rearrangements).

Fig. 1 Strategy for the construction of specific ΦX deletion mutants. The gene G coding sequence is indicated by the heavy black line. *HhaI* 614 (fragment H3) was isolated by procedures similar to those described elsewhere¹⁶. Wild-type ΦX viral DNA was prepared by phenol extraction of a purified phage preparation. Viral DNA (30 μ g) and *HhaI* (5 μ g) were annealed in 200 μ l of buffer (90 mM NaCl, 10 mM $MgCl_2$, 7.5 mM Tris-HCl, pH 8, and 0.75 mM EDTA) by boiling for 3 min, chilling rapidly to 0 $^{\circ}C$ and incubating at 67 $^{\circ}C$ for 2 h. The mixture (50 μ l) was made up to 100 μ l by adding buffers and enzymes to the following final concentrations: 45 mM NaCl, 12.5 mM Tris-HCl, pH 8, 5 mM 2-mercaptoethanol; 0.38 mM EDTA, 100 units ml^{-1} *HincII* (an isoschizomer of *HindII*, Bethesda Research Laboratories). Restriction was carried out for 2 h at 37 $^{\circ}C$ before termination by a phenol extract followed by three ether extractions and dialysis of the DNA against cold 10 mM Tris-HCl and 1 mM EDTA (pH 8). This DNA preparation was ligated at 20 $^{\circ}C$ for 5 h in 400 μ l with buffers and enzyme at the following concentrations: 50 mM Tris-HCl, pH 7.5; 5 mM $MgCl_2$, 5 mM 2-mercaptoethanol, 0.08 mM ATP; 0.25 mM EDTA, 50 units ml^{-1} T4-DNA ligase. The reaction was terminated by one phenol and three ether extractions. The DNA was redialysed against cold 10 mM Tris-HCl and 1 mM EDTA (pH 8). Spheroplasts were prepared as described elsewhere¹⁷ from C600/p $\Phi XG105$ constructed by transforming the K12 strain C600 (Su⁻, ΦX^+) with p $\Phi XG105$ DNA by methods described elsewhere¹. The above ligated DNA (40 μ l) solution was diluted to 400 μ l with 50 mM Tris-HCl (pH 8) and used to transfect 400 μ l of the spheroplast preparation by published procedures¹⁷. Spheroplast lysates plated on the *E. coli* C/K12 strain, HF4738 ΦX^+ Su⁺ recA/p $\Phi XG105$, gave about 10⁷ plaque-forming units per μ l of the ligated DNA preparation. The lysate was screened for lethal mutants by plating on double-layer lawns of HF4738/p $\Phi XG105$ over HF4738. After 7 h at 37 $^{\circ}C$ the plates revealed that 2–5% of the plaques were small and turbid, and the remaining plaques had wild-type morphology (large and clear). Thirty turbid plaques were punched out at random with a capillary. Each plaque was suspended in buffer (50 mM sodium borate, 1 mM EDTA, pH 9). Each suspension was titrated at suitable dilutions on C, HF4738 and HF4738/p $\Phi XG105$, and nine were found to plate on C and HF4738 at a plating efficiency lower than 10⁻⁴ compared with that on HF4738/p $\Phi XG105$. One of these suspensions constituted the seed stock for ΦX GV/FS ZH1.

Here, we report the *in vitro* construction of a site-specific deletion-frameshift mutant, GV/FS ZH1, in which residues 2,513–2,592 (80 bases) of the wild-type sequence have been deleted. This also produces a –2 frameshift in which 14 in-frame, nonsense codons are generated at, and downstream from, the site of the deletion. We will show that this mutation is lethal, but the mutant virus grows in host cells carrying p ΦXG . The procedure we have used for constructing this deletion frameshift is simple and specific. It should be applicable not only to other regions of $\Phi X174$ DNA but also to other interesting DNAs, provided that a system for growing the mutant is available. The results also demonstrate that it should be possible to rescue most $\Phi X174$ gene G mutants regardless of the origin or nature of the mutation.

Construction of $\Phi X174$ GV/FS ZH1

Figure 1 is a scheme of the procedures used for the construction and isolation of the deletion mutant. This involved the following steps. (1) ΦX wild-type replicative form DNA (RF DNA) was cleaved with the restriction endonuclease *HhaI*, and the fragment *HhaI* 614 (H3)³, was isolated. This fragment contains all the translated portion of gene G, 29 of the nucleotides preceding the translated portion of gene G and 49 residues from gene H (ref. 3). (2) Wild-type ΦX single-stranded viral DNA (SS DNA) was annealed with double-stranded restriction fragment *HhaI* 614. (3) The ΦX SS DNA–*HhaI* 614 partial duplex was cleaved with *HincII* (an isoschizomer of *HindII*) at the known *HindII* sites, R9/10 and R10/2 (ref. 3). These cut sites are 79 nucleotides apart and include residue 2,571, the preselected target for our projected modification studies. (4) Without isolation, the specifically shortened, linear, partial duplex was rejoined by blunt-end ligation with T4 DNA ligase to obtain a covalently closed, circular, partial duplex with a unique deletion. (5) Infectious virus particles were produced by transfection of C600/p $\Phi XG105$ spheroplasts with the mixture containing uniquely shortened circular partial duplex DNA. (6) Mutants were selected from the resulting phage population by plating on double-layer lawns of HF4738/p $\Phi XG105$ over HF4738.

In a typical experiment (see legend to Fig. 1), 2% of the phage population obtained after step (5) were mutant by the criterion of plaque formation on HF4738/p $\Phi XG105$ but not on the parent strain HF4738. Three such mutants were randomly selected for further analysis and were found to have similar properties. Most of the experiments described below refer to one of these mutants, named GV/FS ZH1.

Biological characterisation of GV/FS ZH1

Table 1 lists some of the ΦX -sensitive host strains that have been tested for plaque formation with ZH1. (The abbreviation GV/FS ZH1 means a deletion and frameshift mutation in gene G, isolate ZH1. For simplicity, we will mainly use the shortened designation ZH1.) The data show that the mutant will not grow on host strains without p $\Phi XG105$. These experiments demonstrate that the genetic defect in ZH1 is lethal, and is confined to gene G, as p $\Phi XG105$ is a well characterised plasmid known to complement for gene G product(s) alone (refs 1, 2; M.Z.H. and R.W.C., unpublished). Also, in a complementation experiment carried out by methods similar to those described by Zuccarelli *et al.*⁶, the gene H amber mutant, N1 (ref. 7), but not the gene G mutant, am9 (ref. 5) is rescued by ZH1. No infective particles are observed in artificial (freeze-thaw) lysates of the wild-type host, *Escherichia coli* C, infected with ZH1. Thus, a defect in lysis cannot be solely responsible for the lethality of the mutation. ZH1 does not grow on *E. coli* C at either 30 or 42 $^{\circ}C$.

Single-cell, single-burst experiments, as well as one-step growth experiments⁸, revealed that ZH1 has a burst size of about 20 on HF4738/p $\Phi XG105$. Wild-type ΦX has a burst size of 200–300 on a similar strain with or without p $\Phi XG105$ (M.Z.H., unpublished results). We have recently shown that the small burst size of *Gam9* on p ΦXG -bearing strains is attributable to its known polar effect on the expression of gene H (M.Z.H., unpublished results). The low burst size of ZH1 is

Fig. 2 A schematic representation of a part of the physical map of ΦX wild-type RF DNA to show the site of the deletion in *ZH1* (hatched rectangle). Each unit is approximately 100 base pairs. The cutting sites of some relevant restriction enzymes are indicated by vertical arrows identified by the letters A(*AluI*), F(*HinfI*), H(*HhaI*), R(*HindII*) and Z(*HaeIII*). Fragments separated by cleavage at some of these sites³ are shown in parentheses. The coding sequence for gene G principal product is indicated by a thick line.

probably a result of nonsense codons generated downstream from the deletion.

Recombination occurs between *ZH1* and p ΦX G105, although it is quantitatively less than recombination between *Gam9* and p ΦX G105 (ref. 1). The level of recombination is further reduced by at least two orders of magnitude in a *recA*⁻ background (such as HF4738) as compared to a *rec*⁺ background (H514). For example, in one experiment single plaques produced by *ZH1* on plasmid-bearing *rec*⁺ strains, picked after incubation for 5–8 h at 37 °C, showed 1–5% wild-type recombinants, whereas similar plaques formed by *Gam9* showed at least 50% wild type. On a *recA*⁻ lawn, *Gam9* and *ZH1* gave 10^{-4} and 10^{-5} wild-type levels, respectively, in plaques picked after incubation for about 5 or 6 h at 37 °C.

These data show that *ZH1* is a gene G mutant; it is not temperature sensitive, and does not grow on any of the nonsense suppressor strains tested (Table 1). It can be maintained in a stable, apparently normal, virulent cycle on host strains carrying p ΦX G, implying that it is capable of all phage functions except those performed by the gene G product(s). It has a low burst size on p ΦX G-bearing strains, and its recombination frequency with p ΦX G is lower than that of the point mutant, *Gam9*, with p ΦX G.

Characterisation of *G^v/FS ZH1* DNA

ZH1 RF, as well as SS DNA preparations, have electrophoretic mobilities very close to those exhibited by the corresponding

wild-type DNAs on 1% agarose gels. The predicted deletion (approximately 1.5% of the ΦX genome) is not expected to change the mobility of *ZH1* DNA appreciably compared with wild type in these conditions.

The known restriction sites in gene G of ΦX 174 RF DNA and the method of constructing *ZH1*, enable us to draw a new (expected) cleavage map for *ZH1* (Fig. 2). This prediction was examined with five restriction enzymes.

Analysis of cleavage products from *ZH1* RF DNA produced by four restriction endonucleases (*HaeIII*, *HhaI*, *AluI* and *HinfI*; Fig. 3) revealed that 80 ± 3 base pairs have been deleted from wild-type DNA, as expected. Digestion of *ZH1* with *HincII* revealed not only the loss of fragment R10 (79 base pairs), as expected, but also a fusion between fragment R9 (162 base pairs) and fragment R2 (770 base pairs) that flank fragment 10 in the wild type⁹. This generates a new fragment about 930 base pairs long. Our construction strategy was expected to regenerate a single *HincII* site by fusing the left half of the site separating R9 and R10 and the right half of the site separating R10 and R2 in the wild-type DNA⁹. Our results with *HincII* (Fig. 3) show that this expected site was not formed. All the restriction fragments seem to be sharp and, with the exceptions noted above, identical to the corresponding wild-type fragments (Fig. 3). This suggests that except for the deletion, the wild-type sequence has been conserved in *ZH1* to the extent definable by restriction.

To characterise the mutation precisely, we determined the DNA sequence of *ZH1* around the expected site of the deletion as well as around other selected parts of the gene G coding sequence³. The results (Figs 4, 5) unambiguously show the loss of an 80 nucleotide-long sequence extending from base number 2,513 to 2,592 of the revised sequence by Sanger *et al.*⁹. Of these deleted 80 nucleotides, 79 are present in the *HincII* fragment 10. The loss of a single, additional base pair (CG) at position 2,513 eliminates the *HincII* site that would otherwise be regenerated by ligation (Fig. 1). Although we cannot rule out an *in vivo* event for the loss of this base pair, we believe that *ZH1* has been derived from a parent molecule in which this additional loss occurred during *in vitro* manipulations. Some of our original mutant isolates may have the expected deletion of only 79 nucleotides. Except for the deletion, we observe no deviation in the *ZH1* sequence so far determined, compared with the wild-type sequence in gene G (ref. 9).

Fig. 3 Fractionation of restriction endonuclease products from ΦX *G^v/FS ZH1* RF DNA by polyacrylamide gel electrophoresis. The DNA was prepared by infecting *E. coli* C grown in 3XD to 5×10^8 cells ml⁻¹ with ΦX *G^v/FS ZH1* ($<10^{-4}$ wild type) at a multiplicity of infection of 3. Ten min after infection, chloramphenicol was added to a concentration of 30 μ g ml⁻¹ and shaking was continued for 3 h at 37 °C. Lysis, removal of host DNA and ethanol precipitation were carried out exactly as described by Godson and Vapnek¹⁸. The DNA pellet from a 1-l culture after ethanol precipitation was suspended in 20 ml 50 mM Tris-HCl:5 mM EDTA (pH 8). The turbid suspension was extracted three times with phenol using centrifugation to separate the phases after each extraction. The aqueous layer was extracted three times with ether and the solution dialysed against the above Tris-EDTA buffer. The solution was adjusted to pH 12.11 at 25 °C with NaOH. The pH and ionic strength at this step are critical¹⁹. The pH was measured with a radiometer type B glass electrode with a negligible Na⁺ correction in these conditions. The electrodes were standardised with fresh Ca(OH)₂ just before use. The pH was maintained for 10 min at 25 °C before neutralising the solution with HCl. Pancreatic RNase A (20 μ g ml⁻¹; heat treated at 70 °C for 15 min) was added and the solution was incubated at 37 °C for 30 min before concentrating *in vacuo* to ~2 ml and fractionating the DNA on a Sephadex S200 column (2.5 $\times$ 35 cm), equilibrating and eluting with 0.3 M NaCl and 0.03 M sodium citrate, pH 7 (Sephadex G-100 gives similar results). Fractions containing the RF DNA eluted near the void volume as a discrete peak. These fractions were pooled and dialysed extensively against cold 10 mM Tris-HCl and 1 mM EDTA (pH 8). The average yield of this preparation is about 1 mg of RF DNA per l of culture. About 2 μ g of *ZH1* or wild-type RF DNA were digested in 100 μ l with *HaeIII*, *HhaI*, *AluI* or *HinfI* and the products were fractionated on 5% polyacrylamide slab gels¹⁶. The *HincII* digest was end-labelled with ³²P as described elsewhere¹⁶ and fractionated on 10% (a) and 5% (b) polyacrylamide gels. The wild-type fragments affected by the deletion are indicated by solid arrows; the fragment resulting from the deletion is shown by a broken arrow. The approximate size in base pairs is indicated and is based on electrophoretic mobility relative to the known wild-type fragments.

Some consequences of the mutation in *GV/FS ZH1*

Examination of the expected (and partially confirmed) sequence of gene G from *ZH1* (Fig. 5) reveals that the deletion eliminates 27 out of 175 gene G codons. However, a total of 136 gene G codons are affected because of a -2 shift in the reading frame that occurs at the site of the deletion. Thus, the gene G sequence in *ZH1* can code for a polypeptide with a sequence identical to the first 39 amino acids from the amino terminus of the wild-type, gene G spike protein. The deletion creates a -2 frameshift in the 40th codon (residue 2,512, Fig. 5) converting a serine codon (UCA) to an *ochre* codon (UAA). (All the Φ X mRNAs are transcribed from the minus strand of Φ X RF DNA. Therefore, they have the same sense as the viral strand⁴.) Presumably, this leads to premature termination of translation. Downstream from the site of the deletion, there are 13 additional, in-frame, nonsense codons (7 UAA and 6 UGA), and several codons that might allow reinitiation, but translation from any of these possible sites encounters in-frame nonsense codons. Because of this nonsense codon barrier, it seems unlikely that any gene G product large enough to have gene G spike protein function will be coded from *ZH1* DNA. This would explain why this particular mutation is lethal and why complementation is required to produce infectious virus particles.

The generation of nonsense codons also seems to lead to abnormal termination of transcription. Our main evidence for this is the small burst size (~20) of *ZH1* grown in a p Φ XG105-bearing strain compared with that of wild-type Φ X (~300) on the same strain. We believe this is a result of the nonsense codons that are generated downstream from the mutation in *ZH1* and the polar effect of these nonsense codons on the adjacent gene, gene H.

Note that gene G and H products are both essential proteins^{4,5}. Both products are made from polycistronic mRNA(s)¹⁰⁻¹⁴. Cells bearing p Φ XG105 make large amounts of Φ X gene G protein even in the absence of viral infection (M.Z.H., unpublished results). The mutant virus must provide all other required proteins, including gene H product, for an infectious particle to be produced. With certain polar Φ X mutants, such as *Gam9*, production of gene H product is markedly reduced¹⁵. We have shown that this polar effect persists with *Gam9* grown in p Φ XG105-bearing cells, giving

Fig. 4 Autoradiograph of a Maxam-Gilbert²⁰ sequence gel. For this sequence, the *ZH1* *AluI* fragment 3 (Fig. 3) was isolated, end-labelled with ³²P and redigested with *HaeIII* to generate *AluI/HaeIII* ~546 labelled at the *AluI* end by the methods described by Humayun *et al.*¹⁶. Partial chemical degradation products were fractionated on a 25% polyacrylamide-7 M urea gel. Nucleotides are numbered according to Sanger *et al.*⁹. Note the deletion of the wild-type sequence from 2,513 to 2,592. The ambiguity in the first two residues at the 5' end of A3 (bottom of figure) is resolved by the known specificity of *AluI*, AG/CT. Thus, the first two residues must be CT, in agreement with the published sequence.

rise to a small burst size (10–15) that is increased five- to seven-fold by an *amber* suppressor strain (non-permissive by itself) carrying pΦXG105.

The generation of 14 nonsense codons in *ZH1* brings this mutant close to a possible 'worst-case' mutation elicited by a site-specific modification of DNA in this region. Before the isolation of *ZH1*, we considered the possibility that the generation of a large number of nonsense codons would be so polar for gene H that the mutant would not be rescued by pΦXG. Our results indicate that polar effects do not seem to affect our studies as seriously as we had anticipated.

Concluding remarks

The isolation and characterisation of ΦX174 *GV/FS ZH1*, shown here to be a deletion-frameshift mutant at a preselected site in gene G, an essential gene of ΦX174, validates the biological part of the system developed in this laboratory for studying the molecular mechanisms of mutation by carcinogens. We have now shown that nonsense mutations^{1,2}, missense mutations (R.W.C., unpublished results), frameshift mutations (this work) and 'large' deletion mutations (this work) can be isolated using host cells carrying pΦXG. Thus, it should be

Fig. 5 Predicted (and partially confirmed) nucleotide sequence of gene G in *ZH1*. The sequence indicated by a continuous line was determined by us by the Maxam-Gilbert²⁰ technique. The remaining sequence and the nucleotide numbering were those of Sanger *et al.*⁵ In the nucleotide sequence, the sites of some restriction endonucleases are indicated by dotted overlining and are identified by the nomenclature used by Sanger *et al.* (A = *AluI*, F = *HaeIII*, M = *MboII*, Q = *HpaII*, R = *HindIII* and Y = *HpaIII*). For ease of comparison, we have also retained the cutting site identifications (fragments separated by each site) of Sanger *et al.*⁵, but note that the deletion in *ZH1* affects the sizes of some of the fragments produced by restriction. The site of the deletion and frameshift is indicated by an inverted solid triangle. The wild-type translational start signals for gene G (G/START at position 2,395) and gene H (H/START at position 2,931), as well as the wild-type G translational stop signal (G/STOP at position 2,920), which is now out of phase with the G start signal, are identified by solid overlining. Nonsense codons (for example, 8 UAA; OC1, 6 UGA; OP1 and so on) encountered in the same reading frame as the G start signal are identified by asterisks. The sequence of a 39 amino acid-long polypeptide possibly coded by the mutated gene G sequence in *ZH1* (identical to the first 39 amino acids from the N-terminus of the wild-type G product) is indicated.

possible to isolate any mutant that might be produced by a single, preselected, site-specific, covalent modification of ΦX gene G with a given carcinogen. The nature of the mutation(s) produced by the premutational lesion in the parental DNA can then be determined by sequencing the mutant, progeny DNA.

We thank F. Sanger for communicating the revised ΦX sequence before publication; Marie Hayashi, Masaki Hayashi,

P. Howard-Flanders and C. Hutchison III for bacterial and viral strains; L. Morin and O. Bhanot for discussions; M. C. Schneider for technical assistance; D. Boily and H. Annus for help in preparing the manuscript. The DNA ligase was from O. Bhanot. This paper is No. 2 in the series "Molecular Mechanisms of Mutation by Carcinogens". This investigation was supported by grant no. 5 R01 CA16319-04 from the NCI, DHEW.

A search for X-ray pulsations from the Galactic Centre

AN intriguing problem in astrophysics is the determination of the conditions which prevail at the centre of the Galaxy. X-rays can penetrate the intervening dust and gas which obscure visible light from this region, and we show here that they may thus provide a sensitive probe of the hot gas and peculiar objects which may populate the Galactic Centre.

X-ray emission was first detected from an extended ($\sim 2^\circ$) region in the direction of the Galactic Centre by Kellogg *et al.*¹. With the spatial resolution of the Uhuru detector used for that observation, it was not possible to determine whether the emission was diffuse, or whether discrete sources contributed to at least part of the flux from this region (designated GCX). Discrete, albeit short-lived sources were later discovered there—two transients^{2,3} and at least three bursters⁴. Lewin *et al.*⁴ noted that two of the three burst sources might be the same as the above transients. They also pointed out that many burst sources have a 'steady' X-ray component which has a time-averaged luminosity ~ 100 times that of the bursts. It was therefore proposed that the GCX bursters also have steady components which would provide a major part, or perhaps even all of GCX flux. This idea was supported by the subsequent detection of several point sources in GCX^{5,6}, at which time it was also noted that the positions of some of the steady sources were in agreement with the positions of the bursters and transients.

The sky distribution of burst sources⁷ and the absence of pulsations, periodicities, and eclipses in the steady components of many other burst sources⁸ make it plausible that the bursters are Pop. II objects, similar to the 'galactic bulge' and the X-ray emitters in globular clusters⁹. However, there may be other sources in the GCX complex which are not associated with bursters. Some of these might be Pop. I objects which might produce pulsations. Radio observations testify to Pop. I activity near the Galactic Centre: that is, active regions of star formation and the presence of supergiant stars and ionising O and B stars. Therefore, it is not impossible that transient X-ray sources such

as the Be stars A1118-61 and A0535+26, which showed pulsations of 405 s and 104 s respectively^{10,11}, might also be detected at the centre of the Galaxy.

We aimed to determine the nature of the discrete sources in GCX by looking for periodic X-ray behaviour. To do this, we used data taken from long pointing observations of GCX (6.3 h in 1976 Feb and 18.9 h in 1977 Feb) by the SAS 3 X-ray observatory. We used the horizontal tube system¹² which had a 1.7° (FWHM) field of view and spanned the energy interval 2.5-35 keV. The data were analysed using the Cooley-Tukey fast Fourier transform (FFT) algorithm. A complete description of the data reduction techniques is given elsewhere¹³. The sampling length used in this analysis restricted our search to periods > 1.7 s, while the low-frequency noise introduced by spacecraft pointing jitter made the search meaningful only for periods ≤ 40 min.

No periodic X-ray behaviour was detected from GCX. In the energy range 2.5-10 keV the 90% confidence upper limits to pulsations range from $\sim 1.6 \times 10^{-3}$ ct cm⁻² s⁻¹ for periods from 2 to 20 s, to $\sim 1.0 \times 10^{-2}$ ct cm⁻² s⁻¹ for periods of the order of 30 min. These correspond to pulsed fractions of the total GCX flux of 1.1% and 7%, respectively. In the 8-35 keV band these limits range from $\sim 2.3 \times 10^{-3}$ ct cm⁻² s⁻¹ (3.3% of the total GCX flux) for periods $\leq 6 \times 10^3$ s, to 6.7×10^{-3} ct cm⁻² s⁻¹ (9.5% of GCX) for longer periods up to 40 min. (The calculation of the pulsed fractions applies only for a sinusoidal pulsation.)

If we assume, as seems likely, that part of the steady GCX flux is due to the steady contribution from bursters, we note the similarity between these and the other X-ray bursters. For the latter, Cominsky *et al.*⁸ have determined upper limits to the X-ray pulsed fraction of a few per cent (2-66 s) and 10% (66-1,000 s). Therefore, some of the discrete GCX sources may be similar to the other bursters which have been associated with Pop. II type X-ray sources. As noted by Lewin (ref. 14 and refs. therein) the absence of pulsations is not compelling evidence against the proposed binary-neutron star models for the burst sources. The magnetic fields of these objects may have decayed (ref. 15 and refs. therein) or, alternatively, the neutron stars in these systems may never have had strong magnetic fields.

In conclusion, we have not detected any pulsations in the range ~ 2 – $2,000$ s from GCX, a region which is known to contain several point sources. However, a search for periodicities < 2 s and > 30 min would be valuable.

We thank the SAS 3 group for hospitality at MIT and, in particular, Dr John Doty and Lynn Cominsky. F.A.C. also thanks Richard Brenner of the California Institute of Technology for advice on FFT analysis. This work was supported by NASA grant NSG 5197.

The angular size of the high-redshift quasar Q0000–398

THE optically selected quasar¹ Q0000–398 has a redshift² $z = 2.827$. This quasar has been identified with a faint double radio source whose angular extent is 134 ± 40 arc s. As all known high-redshift radio-selected quasars have much smaller angular sizes, it has been suggested that the upper envelope of the angular size–redshift diagram of radio quasars is depressed by an anticorrelation of linear size and radio luminosity³. We show here, first that the radio source associated with Q0000–398 is compact and centred on the optical quasar, and second that there is no evidence in our data on other quasars for the suggested anticorrelation.

We observed Q0000–398 at 1,465 MHz with the partially completed VLA during 16–18 June 1978 as part of a larger programme to study radio emission from optically selected quasars. Nine scans of Q0000–398 were made at uniform intervals within 2 h of transit. All 15 pairs of the six antennas were correlated; baselines from 3,500 to 52,000 wavelengths were available. The synthesised beam is shown in Fig. 1a. The 'clean' map of Q0000–398, restored with an 18 by 3 arc s elliptical gaussian beam, is shown in Fig. 1b.

The only radio source in the field is at 1950.0 position $\alpha = 00^h 00^m 30.29 \pm 0.02$, $\delta = -39^\circ 48' 47.6 \pm 0.8$. It is unresolved (< 6 by 1 arc s) and has a 1,465 MHz flux density of 14 ± 2 mJy. The optical position of Q0000–398, measured from the Whiteoak extension of the National Geographic–Palomar Observatory Sky Survey print, is $\alpha = 00^h 00^m 30.26 \pm 0.13$, $\delta = -39^\circ 48' 49.6 \pm 1.5$. Thus we identify Q0000–398 with a single compact radio source centred on the optical quasar. M. R.

Fig. 1 a, Synthesised beam for the 1,465 MHz VLA observations of Q0000–398; b, The 1,465 MHz VLA map of Q0000–398. Negative contours are indicated by broken lines.

Gearhart (personal communication) has suggested that marginal observing weather coupled with the low elevation of the source may be responsible for the large angular size observed at 2,695 MHz with the NRAO three-element interferometer.

Our preliminary 1,465 MHz VLA maps of other high-redshift quasars indicate that the faint radio sources sometimes associated with optically selected quasars do not have larger angular sizes than the more luminous radio-selected sources.

Martian extratropical cyclones

VIKING Orbiter 1 has recently photographed two cloud formations in the northern hemisphere of Mars which closely resemble satellite pictures of terrestrial extratropical cyclones. The pictures, (Figs 1 and 2) were acquired during the summer season and are the first evidence that baroclinic waves, prevalent during other seasons, also occur in summer. Physical properties of these systems deduced from the vidicon images and from the IR thermal mapping experiment (IRTM) are discussed here.

The north polar region of Mars has long been recognised as one of the most meteorologically active areas on the planet, particularly during winter when the polar cap is obscured by a diffuse hood of condensate clouds. Mariner 9 acquired several images of the region in late winter, $L_s = 342^\circ$ to $L_s = 354^\circ$, which have been analysed in detail by Briggs and Leovy¹. The development of the clouds observed in the region surrounding the seasonal polar cap indicated a circulation pattern consistent with baroclinic waves, which had been predicted previously by Mintz².

Viking Lander 2, situated at 48° latitude, just at the edge of the seasonal cap at its largest extent, has monitored local meteorology for more than one martian year; results of a large part of this mission have recently been reported by Ryan *et al.*³. During the autumn season periodic changes are observed in the pressures and wind vectors obtained by VL-2 (but not by VL-1, located in the equatorial region) which strongly suggest the passage of baroclinic systems to the north of the lander site. These variations were obscured by diurnal variations during the first summer, and the major winter dust storm strongly interfered with the activity.

Viking orbiters were not designed primarily as weather satellites; monitoring for meteorology could only be conducted when the spacecraft were near their respective apoapsides because of the relatively large focal lengths of the telescopes. Such monitoring was severely restricted by orbital constraints and by competition for a limited number of frames with several other activities. During the latter part of the Extended Mission and the

Fig. 1 The martian storm system observed by the Viking Orbiter 1 at (81, 160), $L_s = 105^\circ$.

Fig. 2 The martian storm system observed by the Viking Orbiter 1 at (66, 227), $L_s = 126^\circ$.

Continued Mission VO-1 has been able to perform this monitoring in the north polar region; these two pictures represent a small part of that data set, which characterises the spring and summer seasons in the martian northern hemisphere.

The basic parameters which characterise the storms are given in Table 1. These include the areocentric longitude of the Sun (L_s), the coordinates, the local time of day, and an estimate of the radius of curvature. IRTM data relevant to the storms are presented in Table 2 in the form of brightness temperatures in the five IRTM channels. The 7, 9, 11, and $20\ \mu\text{m}$ channels generally characterise the ground temperatures with small differences produced by dust and condensates in the atmosphere⁴; the $15\ \mu\text{m}$ temperatures are characteristic of the atmosphere at a pressure of 0.6 mbar, equivalent to an altitude of about 25 km. Only limited IRTM data are available for the second storm, owing to the geometry and spatial resolution of the scans.

The IRTM measurements show that a large temperature gradient existed just north of storm 1; the magnitude of this gradient was $\sim 0.2\ \text{K km}^{-1}$, and the change was confined to about 60 km. The area occupied by the spiral cloud is generally characterised by a ground temperature of $\sim 230\ \text{K}$, while temperatures of 215 K are found adjacent to this area to the north. To the south of the storm, between 75° and 80° latitude, there is a gradual rise in the temperature to 237 K. These are precisely the effects which are expected for such a system since the waves which give rise to these disturbances occur in the polar front which separates the frigid arctic air from the warmer mid-latitude atmosphere. The temperature gradient is confined to the lower atmosphere where the clouds are located since there is no structure in the $15\ \mu\text{m}$ data; this is generally expected as only the major dust storms seem to produce pronounced effects at the 0.6 mbar level⁶.

Table 1 Location and scales of the extratropical storms

Storm	L_s	Lat.	Long.	LT	R (km)
1	105°	81°	150°	10.00	100
2	126°	66°	227°	06.33	300

The observed brightness temperatures clearly show that the atmosphere is too warm for the observed cloud to be composed of CO₂ ice particles. The temperature difference between the 9 and 11 μm channels is sensitive to the cloud composition^{4,5}; the negative values of $T_9 - T_{11}$ seen over much of the region suggest a generally dusty background atmosphere, consistent with the appearance of the vidicon images. However, for observations which apparently include the cloud, values of $T_9 - T_{11}$ which are near zero or slightly positive are seen; this strongly suggests a water ice composition for the cloud. Since the interpretation depends on the vertical thermal structure of the atmosphere and as the IRTM resolution is large compared with the detail of the picture, this information is probably not definitive. However, there are several other facts which are consistent with condensate (water) rather than dust.

(1) The albedos associated with the clouds are about 0.3, higher than the surrounding ground and higher than expected for dust.

(2) Comparison of the image in Fig. 1 with a picture taken through the red filter at the same time shows a much larger contrast between cloud and ground in violet than in red; this generally suggests condensate as opposed to dust, as the clouds in the former case are expected to be much more spectrally flat than martian ground or dust.

(3) The water vapour content of the atmosphere is maximum over the north polar region during this season⁷. However, as mentioned, there seems to be dust generally mixed in the atmosphere; the dust may enhance the cloud formation by nucleating the condensation of ice particles to form clouds as air parcels are cooled. This mechanism, the stirring up of surface dust and subsequent nucleation, may be quite important in the seasonal recycling of atmospheric water vapour and in the ultimate formation of the hood.

A dusty atmosphere is also suggested by $T_9 - T_7$, although the 7 μm data points are not conveniently situated for computing this difference in the vicinity of the storm. There is a suppression of the magnitude of the brightness temperature for those IRTM points identified as cloud; this is anticipated, as the increased opacity implies a higher origin for radiation. Unfortunately, two colour coverage of the second storm is not available. However, the limited IRTM data suggest that this cloud is also composed of water ice. The geometry of the scans, and the proximity of the terminator, preclude observation north of this storm, so that there are no direct measurements of expected local temperature gradients.

Table 2 IRTM of the storms (K)

Storm 1	T_7	T_9	T_{11}	T_{15}	T_{20}
Storm area	236	233	233	177	232
Area to north	221	217	218	177	216
Storm 2					
Storm area	216	215	214	167	213

The geometry of the scans prevents observations of the region north of storm 2.

The wind velocity, the pressure gradient, and the radius of curvature determine the force balance for parcels in the storms. The resulting gradient wind, for which the pressure gradient force, the Coriolis force, and the centrifugal force are in balance, is given by

$$v = -fR/2 + ((fR/2)^2 + R|\nabla p|/\rho)^{1/2}$$

where R is the radius of curvature, ∇p the pressure difference, ρ is the density, and f is the Coriolis parameter, roughly the same for Mars as for Earth. The signs are chosen to represent the normal counter-clockwise circulation around a low pressure cell as seems to be indicated by visual interpretation. VL-2 data were used to estimate the appropriate values of mean pressure and of pressure fluctuations to be used

in the formula; a value of $\nabla p = 0.25$ for the amplitude of the pressure difference seems to be a reasonable upper limit which may be used to estimate an upper limit for v .

The resulting wind velocities and accelerations are given in Table 3. The resulting velocities, 31.5 m s^{-1} and 23.1 m s^{-1} for storms 1 and 2 respectively, lead to surface wind speeds of 12.6 m s^{-1} and 9.2 m s^{-1} if a scale factor of 0.4 is used to interpolate between surface winds and winds at the top of the boundary layer¹⁸. These are certainly reasonable when compared with the typical wind speeds observed by VL-2, and the consistency of the force balance supports the interpretation of these systems taken here. The more northerly storm 1, because of its small size, is approximately cyclostrophic while the larger storm 2 is approximately geostrophic¹¹. The predicted near surface wind speed of $\sim 12.6 \text{ m s}^{-1}$ for storm 1 is close to the saltation velocity (Greeley, personal communication), which is consistent with our interpretation that dust is mixed with the ice particles in the atmosphere.

Table 3 Meteorological properties of the storms

Storm	v (m s^{-1})	p/ρ (N T kg^{-1})	fv (N T kg^{-1})	v^2/R (N T kg^{-1})	Vorticity
1	31.5	0.0144	0.0044	0.0100	6.3×10^{-4}
2	23.1	0.0048	0.0030	0.0018	1.5×10^{-4}

In the case of storm 2, cloud shadows are seen which may be used to estimate the altitude of the clouds. This estimate leads to a height of $\sim 6\text{--}7 \text{ km}$ for this system which is similar to the altitudes deduced for many other martian clouds although some clouds have been seen which are 50 km above the surface^{9,10}. This altitude is quite compatible with the temperature suppression effect mentioned earlier: if a linear lapse rate is assumed, the brightness temperatures observed for cloud 1 are appropriate for an altitude of about 4 km, implying that the intervening material is at least that altitude.

In conclusion, two storm systems observed by Viking seem to be similar to terrestrial mid-latitude cyclonic storms in appearance. Water ice is the favoured composition for the clouds. The scales are somewhat different than for terrestrial storms, but this may be associated with the northerly location. Further work is underway to combine these data with other information acquired by the orbiters to prepare an integrated picture of meteorological phenomena in the Mars north polar region.

G.E.H. performed this study as part of the Viking Guest Investigator Program and is supported by the SRC. P.B.J. acknowledges the support of NASA and by NSF Climate Dynamics Programme.

Differential aeolian redistribution rates on Mars

THE surface of Mars gives abundant evidence for aeolian activity, including wind-laid dust and ice deposits at the poles that may be several kilometres thick, a vast dune field surrounding the north polar deposits, a dust mantle of varying thickness covering the high to mid-latitudes, and both depositional and deflationary aeolian landforms in the equatorial latitudes. Two major questions concerned with the martian aeolian activity are: first, what are the rates of erosion and redistribution of surface materials such as rock and soil deposits; and second, are most of the large-scale aeolian features seen on Mars products of the present aeolian environment, extrapolated back through geological time, or were most of the features produced in a different climatic regime? Presumably, a different climatic regime, either associated with an early, denser atmosphere, or with periodic variations in atmospheric conditions induced by obliquity changes, would strongly modulate the vigour of aeolian activity¹. The Viking Orbiters and Landers, which began acquiring data during the summer of 1976, have now monitored the aeolian environment for slightly more than one full Mars year. Data acquired during the mission have enabled us to investigate these questions for aeolian effects averaged over billions of years, tens of thousands of years, and during a single year.

The integral effect of aeolian activity can be sampled over geological time scales by examining the degree of modification of features large enough to be seen by the Viking Orbiters. Figure 1a shows an orbital view over the Viking Lander 1 (VL1) site. VL1 is sitting on terrain which from orbit seems similar to a lunar *mare* surface. Crater counts by Dial³ show that the crater population of this region is in production, at least for crater sizes extending down to 100 m. Craters smaller than that size are less abundant than would be predicted for a population in production. The deficiency of small craters is probably due to information loss, as the image ground resolution is 25 m per line-pair and a feature typically needs to be several times that size to be detectable. Thus, the crater count data constrain the integral effects of aeolian activity over the lifetime of the crater population to values small enough to have only obliterated craters smaller than 100 m in diameter.

Figure 1b is a VL1 frame showing a crater on the horizon. The crater can also be seen on the orbital mosaic. It is about 2 km from the Lander and it is about 420 m in diameter. The rim height to crater diameter ratio for this feature is about 0.12, which compares favourably with the same ratio for the lunar South Ray crater located at the Apollo 16 landing site. The ratio for South Ray crater, which is 640 m in diameter and 2 Myr old, is 0.09 (ref. 4). South Ray is young enough to be virtually untouched by lunar erosion. The similarity in ratios for the two features strongly implies that the crater in Fig. 1b is also preserved virtually intact. In addition, examination of the orbital mosaic shows that all other craters of similar size have raised rims and bowl-shaped floors. No spectrum of morphologies can be discerned, implying that erosion and deposition have been minimal over the lifetimes of these craters. The rim height of the crater in Fig. 1b is 25 m, so the extent of removal of material must have been some small fraction of that number. Such a conclusion is consistent with the crater count data, because the extent of rock breakdown removal has most probably been a few metres over the lifetime of the crater population.

The extent of preservation of the crater population provides excellent data for estimating that lifetime. From our own crater counts we find that there are $\sim 1.5 \pm 0.2 \times 10^3$ craters per 10^6 km^2 larger than 1 km in diameter within a radius of 100 km of the landing site. Neukum and Wise⁵ developed a cratering flux model for Mars by assuming that the flux of impacting objects is the same for Mars and the Moon. They also find after

scaling for impact velocity and gravity effects, that the resultant cratering rate would be 0.22 that of the Moon's rate. Such a model results in an age of about 3,600 Myr for the region surrounding VL1. Given the uncertainties of the martian cratering history the actual age could be a factor of 2 or 3 younger than this estimate⁶. However, for any reasonable cratering flux model, the computed erosion rate of metres per 10^9 yr is surprisingly small, some $10^{-3} \mu\text{m yr}^{-1}$, or $\sim 1 \text{ m}$ per 10^9 yr .

From both orbital and lander views, the VL2 landing site seems quite distinct from the VL1 site⁷. Extensive evidence for differential deflation can be seen from orbit (Fig. 2a,b). The more resistant areas consist of ejecta deposits from craters, while the deflated regions were probably once covered with fine-grained aeolian deposits that were part of the extensive mantle of deposits surrounding the north pole. Relatively rapid

Fig. 1 a, Viking Orbiter 2 mosaic of high resolution frames showing the Viking 1 landing site in Chryse Planitia. The Lander location as derived by Morris *et al.*² and updated by Jones (personal communication). The arrow points to the crater that can be seen in the Lander view shown in b. Crater counts by Dial³ show that the crater population is in production at least down to the counting resolution limit of $\sim 100 \text{ m}$. This result, together with the fresh-looking appearance of the craters and wrinkle ridges suggests that not more than metres of material have been stripped away over the lifetime of this surface. For reference, VL1 is located at 22.5° N , 48.0° W (ref. 2). VO II frames 452B8–12. b, Viking Lander 1 view of the crater delineated by an arrow in a. The crater is about 2 km from the Lander and 420 m in diameter. The rim height to diameter ratio for this crater indicates that little to no erosion has occurred since its formation. For scale, the bottom of the frame covers 3.3 m. VL1 frame A235.

wind erosion of regions not covered by craters and ejecta have left the latter features standing above most of the terrain as plateaus or pedestals. Ejecta deposits may be more resistant to erosion because they are protected by a population of blocks. Blocky ejecta surfaces may form as a result of ejecta emplacement in a debris flow mode⁸. During debris flows, larger blocks are preferentially forced to the surface because of a vertical dispersive pressure within the flow that scales as the square of the block diameter⁹. Thus, a debris flow mode of ejecta emplacement may create a ready-made armoured surface that lasts for a considerable length of time, given the very low rate of rock removal computed from VL1 data.

The extent of deflation between ejecta and surrounding terrain in the vicinity of VL2 is several hundred metres, assuming a conservative estimate of 10° for the slope of the talus between

Fig. 2 *a, b*, Viking Orbiter 2 photograph and sketch map of part of Utopia Planitia. Viking Lander 2 touched down in an area that is just off the upper left edge of the frame. The frame is 90 km across. VL2 is located at 48.0°N , 225.6°W , within the northern mantle of aeolian debris surrounding the eroded polar cap deposits. Only one crater with a sharply raised rim, deep, bowl-shaped floor and extensive ejecta unit can be seen. It is shown on the sketch map as a fresh crater. Most other craters have a pedestal-like appearance. The tongue-shaped plateau extending across the upper part of the frame is a lobe of ejecta from the 100 km diameter crater, Mie, located ~ 200 km to the north-east. The topography of this region is controlled largely by differential deflation; high areas consist of craters and ejecta deposits that have resisted erosion. The deflated material probably consisted of fine-grained aeolian sediments associated with the debris mantle. The fresh crater must post-date any period of extensive deflation. VO II frame 9B16.

the edge of the pedestal craters shown in Fig. 2*a, b* and the surrounding deflation horizon. The antiquity of the terrain surrounding VL2 can be estimated, to a first approximation, from the superimposed crater abundances. An age estimate based on the crater population ($1.4 \pm 0.2 \times 10^3$ craters per 10^6 km^2 larger than 1 km) shown in Fig. 2*a* and surrounding areas would be about 3,400 Myr with the flux model used for the VL1 site. The average deflation rate would thus be very roughly 100 m per 10^9 yr, which is less than $1 \mu\text{m yr}^{-1}$. The estimate is several orders of magnitude greater than the rate of rock erosion derived for the VL1 site and, by implication, for the armoured ejecta deposits at the VL2 site.

Constraints can also be imposed on the integral effect of aeolian activity averaged over time scales of tens of thousands of years. Windblown drifts seen at both landing sites have morphologies indicative of accumulation during a prevailing north to south wind regime—the situation prevalent during the annual global dust storms occurring near the time of perihelion^{10,11}. Surface winds during the global perihelion storms seem to carry near surface dust in a net north to south direction in areas to the north of the subsolar latitude at perihelion (the SLP; presently located at $\sim 15^\circ\text{S lat.}$) and in a net south to north direction in areas more southerly than the SLP. A complex but generally west to east flow seems to dominate the SLP proper¹¹. Most of actual entrainment of dust that feeds the global dust clouds seems to be concentrated in a wide latitude belt centred about the SLP, giving rise to the speculation that the major dark areas of Mars, which roughly coincide with the SLP, have been stripped of a thin, bright dust cover¹². That dust cover would now reside in other regions in the form of deposits such as the drifts at VL1 and VL2. Due to precessional effects, the SLP migrates $\pm 25^\circ$ in latitude about the Equator over a 50,000 yr time span¹³. Because of the enhanced stripping associated with regions close to the SLP, it seems probable that the drifts at VL1, with their strictly north to south trend, must have accumulated since the SLP was last over the landing site latitude (24°N lat.), which would have been about 15,000 yr ago. Presumably drifts with west to east trends, or perhaps a stripped surface, would have dominated the surface at that time. If this line of reasoning is accepted, then a net accumulation rate of about 10 cm (mean drift thickness) per 15,000 yr, or several $\mu\text{m yr}^{-1}$, can be computed.

Figure 3 shows a pair of Viking Lander 2 (VL2) pictures acquired 476 martian days apart. The striking difference is related to the deposition of a thin layer of bright dust during the second major dust storm that occurred during the Viking mission. The dust is detectable only by its increased brightness; even then, it is only detectable in pictures acquired at high Sun angles (low phase angles). This constraint implies that the dust layer is probably only micrometres thick¹⁴. So far, no significant erosion of the new dust deposit has taken place, although such an accumulation, without subsequent erosion, cannot occur over more than a few tens of thousands of years without burying the boulders exposed at the landing site. Conditions at VL1 have been similarly quiet, with the accumulation of a bright dust layer, again probably only micrometres in thickness, being the dominant activity¹⁴. Thus, both landing sites have experienced an aeolian environment that, averaged over a yearly time scale, has resulted in the redistribution of several micrometres of dust. Such a conclusion is consistent with Lander camera observations of atmospheric opacity during the same time frame, which suggest dust transport rates of about $3 \times 10^{-4} \text{ g cm}^{-2} \text{ yr}^{-1}$ (ref. 15). Deposited evenly over the surface, such a rate equates to a dust layer of about $1 \mu\text{m}$ in thickness.

Our results for the Viking Landing sites indicate that little rock breakdown and removal by wind has occurred over approximately the past 3,000 Myr. On the other hand, relatively rapid redistribution of friable or loose, fine-grained materials has occurred. Many of the landforms seen in higher resolution Viking Orbiter frames covering other parts of Mars are consistent with such interpretations. Many volcanic flow fronts, well preserved crater populations, and other features which are

Fig. 3 The top VL2 frame was acquired 32 d after landing, during the Northern Hemisphere's summer season. The bottom frame was acquired 476 d later, with identical lighting. The brightness difference is related to an accumulation of several micrometres of bright dust during the second global dust storm that occurred during the martian year of Viking observations. The top frame is B013 and the bottom is G052.

indicative of little to no significant modification can be discerned. In other regions, the surface has been stripped, yardangs have formed, and in general the topography seems to have been largely configured by aeolian activity. Such regions must be composed of friable deposits, such as volcanic ash or older aeolian materials. Finally, the similarity of redistribution rates for aeolian deposits averaged over three vastly different time-scales implies that roughly the present aeolian environment has been operative for a significant fraction of geological time.

We thank Linda Miller for manuscript preparation and J. Veverka and R. Greeley for reviews. This research was supported by NASA Headquarters Planetary Geology Program grant NSG-7087 and by NASA subcontract 955248 from the Jet Propulsion Laboratory.

Gravitational magnetism

BLACKETT¹ has pointed out that the ratios of magnetic moment to angular momentum for Earth, the Sun, and the star, 78 Virginis, are nearly equal and of a magnitude which suggests a gravitational origin for the magnetic fields of these bodies. After his laboratory experiment testing this hypothesis yielded negative results², gravitational magnetism became largely ignored. Recent magnetic field measurements of the moon³, Mercury⁴, and Jupiter⁵, however, yield ratios quite close to that considered by Blackett. Moreover, Russell⁶, who emphasises only the phenomenology of these ratios and eschews any physical model, adds Venus and Saturn to the list, although these data are tentative and will become firm only with the completion of probes to Venus and Saturn. His re-evaluation of Mars, however, puts this planet into an exceptional position as it seems to have no measurable magnetic field. I agree with his suggestion that to account for this we must ultimately consider the interiors of the planets. Hopefully more precise magnetic measurements will be made on Mars. Meanwhile a new data point strengthens the gravi-magnetic hypothesis: the magnetic field of a pulsar—Hercules X-1—has been directly measured^{7,8} and yields the Blackett ratio. Because the Hercules data is both fairly exact and represents an extremely high magnetic field (5×10^8 T) and angular velocity (5 rad s^{-1}), it is appropriate to reconsider Blackett's gravi-magnetic hypothesis, and I show here that the gravi-magnetic hypothesis has yet to be tested definitively in the laboratory.

The gravi-magnetic hypothesis proposes that a rotating mass, measured in gravitational units, has the same magnetic effect as that of a rotating charge, measured in electrical units. The respective force constants determine this relationship

$$G^{1/2}m = k^{-1/2}q \quad (1)$$

where G is the gravitational constant, m is mass, k is the Coulomb constant, and q is electric charge. Thus the ratio of magnetic moment to angular momentum for a sphere of mass, m , density factor, f , radius, r , angular velocity, ω , and magnetic field, B , is (in SI units)

$$P/U = 5/4 \pi B / \mu_0 r / \rho \omega m = G^{1/2} / 2k^{1/2} \quad (2)$$

Table 1 and Fig. 1 show the degree to which this expectation is met: the data points in Fig. 1 fit the $G^{1/2}/2k^{1/2}$ line remarkably well.

Note that the mere fact of a linear relationship between the magnetic moments and angular momenta is not what is surprising in these data. *A priori*, we should expect a correlation between P and U . In equation (2) we expect r to be correlated with m , and B to be correlated with ω ; and thus, we expect P to be correlated with U . The surprise is that this correlation ratio, P/U , should turn out to be close to $G^{1/2}/2k^{1/2}$. Without the gravi-magnetic hypothesis, there is no reason to expect the regression line for the data of Fig. 1 to be close to $P = G^{1/2}/2k^{1/2} U$. If we have only one datum point, and it has a P/U close to $G^{1/2}/2k^{1/2}$, we should be surprised enough to take notice of the gravi-magnetic hypothesis. However, that one datum point may not turn out to be typical. The value of Fig. 1 is in showing that the data points typically fall close to the gravi-magnetic hypothesis line. The only atypical point, thus far, is Mars. The gravi-magnetic hypothesis (stated in $\log_{10}$ form) predicts a P/U of -10.37 . The mean P/U for the data points plotted in Fig. 1 is -11.13 with a standard deviation of 0.42.

As we have no *a priori* way of knowing the likelihood of the near coincidence of P/U with $G^{1/2}/2k^{1/2}$, it may be useful to calculate how easily the data points can be pulled away from the gravi-magnetic hypothesis line. To do this, we must take into account the interdependence of the variables: r , m , B , and ω . Thus, if one changes r , the other variables would be expected to change in accordance with this dependence. There are two

Table 1 Maximum and minimum data for ratio of magnetic moment to angular momentum for massive bodies

* For neutron stars, the larger mass is associated with the smaller radius²¹.

[†] $G^{1/2}/2k^{1/2} = 4.3 \times 10^{-11} \text{ C kg}^{-1}$.

measures of this dependence. First, each datum point has its own dependence relations. Second, there is a set of mean dependence relations for the data as a whole. Thus for all the data points (except 78 Vir and Her X-1)—in log₁₀ form, and in SI units—the mean of the ratio m/r is 3.57 (s.d. = 0.11); the mean B/r is -0.726 (s.d. = 0.35); the mean ω/r is -0.701 (s.d. = 0.21).

If one changes r for each datum point (except 78 Vir and Her X-1) by an order of magnitude, and changes m , B , and ω according to the individually calculated dependence relations, P/U for each datum point will change by more than two orders of magnitude. The mean P/U for these changed data points will be -13.95 (s.d. = 0.47), compared with the mean P/U of -11.18 for the unchanged data points.

A greater change than this will occur if one uses the mean dependence relations mentioned above. In this case the mean P/U for the changed data points will be -14.20 (s.d. = 2.21).

Since r in Table 1 ranges over five orders of magnitude, a change in r of one order of magnitude is relatively small, and thus we can say that the data points are sensitive to relatively small changes in the relevant variables.

A striking characteristic of the data in Fig. 1, is that the deviation from the gravi-magnetic hypothesis line is fairly systematic. It should be obvious, of course, that deviations from the $G^{1/2}/2k^{1/2}$ may well be due to electrical-magnetic effects. For example, equation (2) predicts a surface field about three times greater than that measured at the surface of the Earth. However, because of the offset between the magnetic and gravitational poles of Earth, electrical-magnetism must also be at work. Whatever accounts for this electrical component of the magnetic field of Earth must also account for the damping of the gravitational component.

The *modus operandi* of the electrical component may also help account for the deep mine measurements of Runcorn^{9,10}, which show the magnetic field increasing towards the centre of the Earth. Blackett² regarded these measurements as decisive evidence against his gravi-magnetic hypothesis, because the gravi-magnetic hypothesis, taken by itself, predicts that the magnetic field will decrease in this direction. This evidence, however, is not decisive. To see this, we must solve equation (2)

for the magnetic field B . The expected magnitude is thus seen to be

$$B = 4/5 \mu_0/4\pi G^{1/2}/2k^{1/2} f \omega m/r \quad (3)$$

For a given body, f and ω remain constant, yielding m and r as the only variables. M , for a uniformly dense sphere, is a linear function of volume— $4/3 \pi r^3$. However fast r falls off in the denominator of equation (3), m in the numerator falls off faster. B thus decreases as r decreases.

To counter the decisiveness of Runcorn's measurements, one must first note that the Earth is not a uniformly dense sphere, so that m is a function of density as well as of volume. As density increases towards the Earth's centre, the decrease in B expected from the gravi-magnetic equation (3) is not as precipitous as the above volume argument might lead one to expect. At the Earth's surface, for instance, equation (3) predicts a B of 2.1×10^{-4} T. This is not, however, a great deal more than the 1.4×10^{-4} T that equation (3) predicts for the surface of Earth's core. More importantly, this core magnetism predicted by the gravi-magnetic equation is greater than the magnetic field of 6×10^{-5} T measured at the Earth's surface. Runcorn^{9,10} measured an increase of about 7×10^{-9} T over Earth's surface field of 6×10^{-5} T, still approximating 6×10^{-5} T, and considerably less than the 2.1×10^{-4} T predicted by gravi-magnetism for Earth's core. This is what we expect if we suppose that gravitational magnetism is modified by an electrical-magnetic effect stronger at the Earth's surface than in the interior. Runcorn's measurements are thus not decisive.

A decisive test for gravitational magnetism must be with laboratory-sized samples. Although Blackett's experiment² gave the appearance of being such a test, I now argue that this and other experiments have not definitively tested the predictions of the gravi-magnetic hypothesis, but only various extra assumptions, which were necessary at the time to predict effects large enough to be seen in laboratory-sized samples.

Wilson¹¹ exploited an ambiguity in the most general form of the gravi-magnetic hypothesis, which states that a mass moving either translationally or rotationally generates a magnetic field, just as a charge moving either translationally or rotationally

generates a magnetic field. There is a great difference, however, between translational and rotational movement. The former is relative, in the sense of special relativity; the latter is not. For charge, a translational movement does set up a magnetic field relative to the motion of the observer, a fact which was the starting point for Einstein's theory of relativity. Thus, although the observational basis for gravitational magnetism is only that massive rotating bodies possess nearly proportional magnetic fields, Wilson wrongly assumed that equation (3), which predicts the magnitude of the gravi-magnetic effect, could be made completely parallel to the electrical case by writing it in velocity form and assuming this velocity to be relative. Thus he had

$$B = 4/5 \mu_0/4\pi G^{1/2}/2k^{1/2} m v/r^2 \quad (4)$$

Because linear velocity is relative, Wilson could swing an iron bar in the laboratory and with his assumptions, consider that it was the Earth with all its mass that was moving past the bar. He thus put the Earth's mass and radius into equation (4) and expected a measurable field of 10^{-7} T. Wilson found that no field of such magnitude exists for laboratory-sized bodies in linear motion, thus ruling out the linear version of the gravi-magnetic hypothesis.

Swann and Longacre¹² tried a different idea. Swann¹³ had shown that by rewriting equation (4) in density form (where ρ is density)

$$B = 8\pi/15 \mu_0/4\pi G^{1/2}/2k^{1/2} \rho \omega r^2 \quad (5)$$

and replacing $\rho \omega r^2$ in equation (5) with $\rho \omega^4 r^4$, magnetic field ratios of the correct magnitude for Earth and the Sun can be predicted as well as measurable magnetic fields for rotating bodies of small mass. The substitution of $\rho \omega^4 r^4$ for $\rho \omega r^2$, however, makes equation (5) dimensionally incorrect, Swann therefore had to add arbitrary parameters to yield correct magnetic moments. This *ad hoc* procedure yielded a field expectation of about 10^{-7} T for a 20 cm copper sphere spinning at 200 Hz. Swann and Longacre spun such a sphere and showed that no field existed, to the limits of their measuring equipment, which was on the order of 10^{-8} T. Swann's version of equation (5) was thus ruled out. The Swann-Longacre experiment,

Fig. 1 Magnetic moment/angular momentum diagram. Comparison of gravi-magnetic hypothesis line, $P = (G^{1/2}/2k^{1/2}) U$, with P and U for massive rotating bodies. The dotted line is the regression line for the data. In $\log_{10}$ form, and in SI units: $G^{1/2}/2k^{1/2} = -10.37$; the mean P/U is -11.13 ± 0.42 .

Table 2 Laboratory experiments testing gravitational magnetism

Experiment (refs)	Assumption (equation number)	Expectation (T)*	Sensitivity (T)	Result
Wilson ¹¹ (1923)	Translational effect field due to mass and radius of Earth (4)	10^{-7}	10^{-8}	0
Swann & Longacre ¹² (1928)	Special rotational effect: $\rho \omega r^2$ becomes $\rho \omega^4 r^4$ (5)	10^{-7}	10^{-8}	0
Blackett ² (1952)	Virtual charge effect, static-body field due to rotation of Earth (4)	10^{-12}	10^{-13}	0
SQUID ¹⁴ (future)	Simple rotation effect, field due to rotating mass of laboratory-size body (3)	10^{-12}	10^{-13}	?

* 1 T = 1 tesla = 10^4 G (of B).

however, did not rule out the simple rotational version of the gravi-magnetic hypothesis, as this version of equation (5) yields a prediction of 10^{-13} T, which was five orders of magnitude below the sensitivity of their measuring apparatus.

After a gap of two decades, Blackett¹² took up the challenge of a laboratory test, encouraged by the new data from 78 Virginis which fit the gravi-magnetic hypothesis. However, Blackett, like Swann and Longacre before him, could not devise an instrument capable of measuring in the range of 10^{-13} T generated by a laboratory-sized spinning body. But he could measure the field of a static body, even if the field was only 10^{-12} T. Blackett therefore investigated a version of the gravi-magnetic hypothesis which predicted a static-body field on the order of 10^{-12} T. According to this version, a rotating body, such as the Earth, by reason of its mass, sets up a virtual electric current, so that a measuring instrument at rest on its surface registers a magnetic field on a small mass which is also at rest; both the small mass and the measuring instrument participate in the Earth's rotation, so that their velocity component, which is due to the Earth's rotation, can be put into equation (4). Thus Blackett calculated a field expectation of 10^{-12} T for a 15 kg mass at rest; and by clever experimental procedures he was able to rule out such a static-body field. He regarded this negative result as a confirmation of Runcorn's results which had been announced just as his own experiment was starting.

Such a catalogue of negative results has perhaps caused physicists to lose sight of the fact that a definitive test of the simple rotational version of the gravi-magnetic hypothesis has never been carried out in the laboratory. A definitive experiment may now be possible and should be attempted. Blackett² himself pointed out that a 1-m bronze sphere spun at 100 Hz (its maximum safe speed) should, on the simple rotational gravi-magnetic hypothesis, yield a field of 10^{-12} T. Such a field can be measured by a SQUID magnetometer¹⁴ limited by an internal field of only 8×10^{-14} T (r.m.s. per root cycle). Table 2 summarises this experimental situation.

Low-level air flow over the western Indian Ocean as seen from METEOSAT

DURING the northern summer, the low-level air circulation over the Indian Ocean is characterised by cross-equatorial flow from the Southern to the Northern Hemisphere. The south-east trade winds of the Southern Hemisphere are sucked in by the zone of continental low pressure located over central India and are mainly deflected by the Coriolis force after crossing the Equator; they give rise to the south-west Indian monsoon and associated precipitation during the summer months¹. The cross-equatorial air flow is not uniform at all longitudes: it is weak over the eastern Indian Ocean and particularly strong along the East African coast, where it is concentrated into a low-level jet (maximum intensity 30 ms^{-1} at between 1 and 3 km) flowing to the Somalia coast from the northern tip of Madagascar². We now report the first results from a study of the low-level airflow circulation over the western Indian Ocean and more particularly the Somali low-level jet stream. Successive images taken by the European geostationary satellite METEOSAT were used to determine wind vectors.

Fig. 1 METEOSAT view of the Indian Ocean on 16 July 1978, at 12.00 GMT.

Fig. 2 Wind vectors determined from cloud displacements on 11 July 1978.

The Somali jet can have a regulating effect on monsoon precipitation over the Indian sub-continent, and a correlation has been found between the amount of rainfall over the western coast of India and the intensity of low-level equatorial winds over Kenya². It has also been found that cross-equatorial winds are stronger during a good monsoon year than during a bad one. The complete structure of this jet is largely unknown because it flows mainly over the ocean. For example, fluctuations of its intensity over Kenya, where it can be studied, may reflect a longitudinal shift of the core of the jet rather than a temporal variation of the intensity. The structure of the jet was intensively studied with an instrumented aircraft for a few days during MONEX-77, but no long-term investigation of variations and geographical extension has been made—this would be particularly difficult with conventional observations because of the marine extension of the jet. However, a geostationary meteorological satellite taking images at intervals would allow such a study from the analysis of cloud displacements. METEOSAT can serve this function and has been working since the end of 1977. It gives a view of the western Indian ocean up to about 60°E and is positioned in the neighbourhood of longitude 0° . METEOSAT produces images of the Earth and its cloud cover every half-hour in three spectral bands—one band in the visible spectrum and two in the IR spectrum (thermal IR, $10.5\text{--}12.5 \mu\text{m}$, and water vapour IR, $5.7\text{--}7.1 \mu\text{m}$, bands) with a ground resolution of 2.5 km for the visible channel and 5 km for the IR channels. From successive images cloud elements can be tracked to infer wind vectors.

The displacement of each cloud element can be determined by using the optical correlator built in our laboratory. This apparatus makes it possible to visualise several successive high resolution images on film loops and to move each image in relation to the others. Pictures can be aligned very precisely by using the landmarks; cloud motions are then measured by moving the pictures in such a way that the observed cloud appears motionless during the film loop; the relative displacements of the

pictures and the location of the cloud elements are recorded and the results are processed on a computer that plots them on a map. This method is relatively laborious but is very precise and moreover, the operator himself chooses the cloud element. In this study, three images were used: two successive visible images taken around noon and a thermal IR image taken at the time of the first visible image. The loop is made with the two successive visible images, and the IR one is used to discriminate the level of the clouds.

At low levels, the deviation between cloud vectors and raw wind data is often small—less than 5 knots. Three factors which might contribute to this error are: (1) an error in the tracking of the clouds; (2) a wrong height given to a cloud vector; and (3) a wrong cloud vector due to its displacement by non-advective effects (for example, orographic clouds or clouds related to local thermal effects). The first error is minimal when an optical correlator is used. The second one is the most difficult to exclude: for convective clouds the level of the top can be easily found on the IR picture, but the cloud motion more closely follows the wind near the base of the cloud. When the cloud top is not higher than the 600 m bar level, the wind given is assumed to be representative of the 900 m bar level. This is particularly so over the Indian Ocean where the trade winds are relatively deep. The third kind of error cannot be detected by objective techniques: it is very weak over the ocean but increases over land.

From METEOSAT low-level clouds (cumulus) are clearly visible over the entire marine region except for the northern Somalia coast, where the cold Somali oceanic current inhibits cloud activity (Fig. 1). Intensive convective activity prevails over Madagascar where it is difficult to infer wind vectors due to orographic effects. Over the flat land of Kenya and southern Somalia, wind vectors can be deduced from cloud motions within the low-level jet. Over the African continent and outside the region where the Somali jet is flowing, cloud motions are very weak and it is difficult to infer wind vectors, as the clouds are related to local convective phenomena.

Figures 2 and 3 give examples of raw wind vectors (not interpolated on a grid) as deduced from cloud motions on two days of the 1978 summer monsoon (11 and 16 July). It can be seen that data cover a large part of the western Indian Ocean. The only regions for which there are no data are certain parts of the African continent, the Arabian peninsula and the marine region off the northern Somali coast. The low-level wind field agrees quite well with previous studies based on conventional but scarce data⁴. On 11 July (Fig. 2) the Somali jet is clearly visible. It flows from the east of the northern tip of Madagascar to Africa where it can be seen over the flat lands of eastern Africa before flowing towards India. The results illustrate the importance of the mountainous ranges from Kenya to Ethiopia and of the Madagascar barrier. Strong winds can be seen around the Mascarene Islands showing that the roots of the jet may be found to the east of 60° E. North of the Equator the Coriolis force deflects the air and gives rise to westerlies over the Arabian Sea. An interesting feature of the clockwise gyre of air concerns its geographical extension. Thus on 11 July it was particularly large (larger than deduced from conventional data) and at the Equator strong winds can be found from 40° E to 55° E; the core of the jet is located close to the African coast. Another feature seen in Fig. 2 is a well-defined depression over Sudan corresponding to the early stage of an African easterly wave.

On 16 July (Fig. 3) the wind field was quite different. The Somali jet can also be seen but only to the north of 10° S and it is very weak. An intensification can be noted over the western Arabian sea off the Somali coast. The geographical extension is very weak and the root in the Mozambique channel is stronger than on 11 July. The most intriguing feature is the wind discontinuity found to the east of Madagascar; it seems to be related to the weakening of the low-level jet. This discontinuity corresponds to the normal deflection of the winds by a frontal zone moving westwards in the Southern Hemisphere. As can be seen in Fig. 1, this frontal system is associated with a mid-latitude cyclonic perturbation centered far south of Madagascar.

Thus extra-tropical systems of the Southern Hemisphere may interact with the cross-equatorial flow of the monsoon. This point needs further consideration with a study using wind fields on days around 16 July.

Fig. 3 Wind vectors determined from cloud displacements on 16 July 1978.

Our preliminary study has shown that the large-scale features as well as the temporal fluctuations of the Somali low-level jet can be studied from successive images taken from a geostationary platform. Since a complete view of the western Indian Ocean can be obtained, the causes of the fluctuations may be found. A daily extensive study was performed, covering 15 days in July 1978 as well as the end of May during the onset of the Indian summer monsoon. Our work stresses the value of a geostationary satellite over the western Indian Ocean region. Thus GOES-1, taking images of the Indian Ocean during MONEX-79, will be an important component of the MONEX observational systems.

We are grateful to the European Space Agency for providing us with the METEOSAT images.

Stratospheric aerosol optical thickness measurements at 35°S

IN the stratosphere the attenuation in the radiance of a light beam is predominantly due to scattering by air molecules and aerosols, and absorption by ozone. For the height range 10–30 km, aerosols can account for at least 60% of the attenuation at 700 nm (ref. 1) and are responsible for most of the long and short term variations². During 1969–76 the stratospheric optical thickness due to aerosol scattering was measured at Adelaide 35°S, using a lidar³. The observations reported here show that the aerosol optical thickness varied by more than a factor of three during that time.

The transmittance⁴ of the atmosphere, $T(h_1, h_2)$, between heights h_1 and h_2 is a measure of the fractional attenuation of a vertically directed beam and is given by

$$\begin{aligned} T(h_1, h_2) &= T_M(h_1, h_2) T_A(h_1, h_2) T_O(h_1, h_2) \\ &= \exp \left[- \int_{h_1}^{h_2} \{ \beta_M(h) + \beta_A(h) + \beta_O(h) \} dh \right] \\ &= \exp [-\tau_M(h_1, h_2) - \tau_A(h_1, h_2) - \tau_O(h_1, h_2)] \quad (1) \end{aligned}$$

where β_M and β_A are the molecular and aerosol volume scattering coefficients, β_O the ozone volume absorption coefficient, and τ_M , τ_A and τ_O are the respective optical thicknesses. For lidar studies it is necessary to introduce the volume scattering function $B(\theta, h)$ which is a measure of the radiation scattered per unit solid angle in the direction θ at the height h in the atmosphere. The total radiation scattered out of a beam is given by

$$\beta(h) = \int_{4\pi} B(\theta, h) d\omega$$

and the fraction of the scattered radiation directed in the backwards direction per unit solid angle is given by $F(\pi) = B(\pi, h)/\beta(h)$. Then the transmittance due to aerosols, $T_A(h_1, h_2)$, between the heights h_1 and h_2 can be related to the integrated backscatter function by

$$\begin{aligned} -\ln [T_A(h_1, h_2)] &= \tau_A(h_1, h_2) = \int_{h_1}^{h_2} \beta_A(h) \\ &= F_A^{-1}(\pi) \int_{h_1}^{h_2} B_A(\pi, h) dh \quad (2) \end{aligned}$$

For the stratosphere suggested values of $F_A(\pi)$ range between 0.013 (refs 5, 6) and 0.0199 (ref. 7).

The laser power $p(h)$ returned from a height h and detected by the lidar receiver is given by

$$p(h) = P_0 K T^2(0, h) [B_M(\pi, h) + B_A(\pi, h)] / h^2$$

where P_0 is the power transmitted, K is a system constant which includes the geometry and efficiency of the lidar optics and electronics, and $B_M(\pi, h)$ and $B_A(\pi, h)$ are the volume back-scattering functions for air molecules and aerosols at the height h . Rearranging gives

$$\begin{aligned} B_A(\pi, h) &= p(h) h^2 / \{ P_0 K T_M^2(0, h) \cdot T_O^2(0, h) \cdot T_A^2(0, h) \} \\ &\quad - B_M(\pi, h) \quad (3) \end{aligned}$$

The solution of equations (2) and (3) for B_A and T_A is accomplished by an iterative technique developed by Elterman⁸. At the height or heights where the total scattering is a minimum the aerosol scattering is assumed to be zero, thereby normalising the lidar signal to the known molecular atmosphere at these heights. This procedure is justified by the detection of regions of very low aerosol content by direct sampling techniques. Values of B_A and T_A are then determined for successive height increments by iteration of equations (2) and (3) at each level. The

Fig. 1 Yearly means values of aerosol backscatter coefficient B_A . Error bars are ± 1 standard deviation.

constant $F_A(\pi)$ was taken as 0.0199; a choice of 0.013 would have changed the integrated backscatter function for the average of the data for 1969 by <2%. The molecular parameters B_M and T_M are calculated from the atmospheric density profile measured by radiosonde balloons launched from the Adelaide Airport, 7 km from the lidar site, on the night of the lidar measurements or on the following morning. The ozone transmittance was calculated from Eltermans tables¹.

The average yearly profiles of $B_A(\pi, h)$, shown in Fig. 1, show how the values of this function have varied with height and time. Error bars represent one standard deviation and include the statistical error in the signal photoelectron count rate and a 1% error⁹ in the radiosonde-measured density profile. Note that although each nightly profile was normalised to the molecular profile in one or more regions, the average profiles for some years show no region where the aerosol contribution to scattering is consistently zero. Failure of the ruby laser allowed only one observation between December 1973 and February 1976.

By integrating curves similar to Fig. 1 over the height range 10–30 km, the vertically integrated aerosol backscatter function^{6,10} is formed; the average monthly values are plotted in Fig. 2. The aerosol optical thickness is indicated by the scales on the right. Scale A refers to a value of $F_A(\pi)$ of 0.0199 and scale B to value of 0.013.

A maximum in aerosol optical thickness occurred in late 1969 followed by a decline thereafter until 1976. The occurrence of the peak value is related to the eruption of the Fernandina volcano in June 1968 and its timing is possibly a result of the gas-to-particle conversion rate¹¹ and the stratospheric meridional transport rates. There is a suggestion of an annual

Fig. 2 Monthly mean values of vertically integrated backscatter coefficient (10–30 km), and corresponding values of aerosol optical thickness assuming values of $F_A(\pi) = 0.0199$ (scale A), and 0.013 (scale B).

variation in 1969 and 1970 with lower values early in the year. The abnormally high value in May 1973 and low value in June 1975 are each the result of observations on a single night and may not truly represent the average conditions in these months.

The peak values of aerosol optical thickness range between 0.013 and 0.020 (depending on the assumed value of F_A). These are considerably less than the values for 700 nm determined by Elterman from searchlight measurements in 1964 and 1965¹ (0.027) and are also less than his value for 1970¹². The average Adelaide value for 1973 is between 0.005 and 0.007. This is higher than the lidar-derived value of 0.004 obtained over California¹⁰ for the same period, but much lower than Elterman's¹ value of 0.014 for the 'normal' stratosphere (when converted to 694 nm). The average of values for early 1976, 0.006–0.009 is slightly higher than the 1973 average and may indicate the presence of some residual dust from the eruption in October 1974 of Volcán de Fuego in Guatemala.

To obtain a reliable estimate of the minimum value optical thickness for the period of observation, a weighted average was calculated from those eight monthly values which were not statistically distinguishable from the lowest value. A value of $(7.4 \pm 0.2) \times 10^{-5}$ per steradian was obtained for the integrated backscatter function, which corresponds to an optical thickness of between 0.004 and 0.006. Thus the extreme values of aerosol optical thickness varied by a factor of at least three during the period 1969–76.

To relate the aerosol optical thickness for the lidar wavelength of 694 nm to the optical thickness for the solar spectrum, the extinction due to scattering was calculated for the two spectral distributions using the stratospheric aerosol size distribution given by Bigg¹³. The extinction of solar radiation is 87% of that for monochromatic radiation at 694 nm. Thus during the period 1969–76, the optical thickness of stratospheric aerosols for solar radiation varied from about 0.018 to 0.004.

An estimation of the reduction in the ground level solar flux at Adelaide during 1969–76 due to stratospheric aerosols can be obtained from the analysis of Cadle and Grams¹⁴. The energy lost due to upward scattering from a solar beam incident at a zenith angle of 60° varied between 0.5 and 0.15%.

Anomalous results for tidal flow through the Pentland Firth

THE flow of water across the vertical component of the Earth's magnetic field induces a potential gradient in the water; measurements of the difference in voltage between the opposite sides of a tidal channel provide an indication of the magnitude of the tidal flow. Longuet-Higgins¹ derived the relationship between the potential gradient and the tidal flow for the case of

uniform flow in a channel of semi-elliptic cross-section. By recording the difference in potential between the ends of submarine telephone cables valuable measurements have been obtained of flow through the Dover Strait^{2,3} and through various channels in the Irish Sea^{4,5}. However, recent cable measurements for tidal flow through the Pentland Firth are shown here to include anomalous results.

The study of the movement and dispersal of certain water masses over periods of years and, consequently, over large spatial zones is of increasing interest in connection with studies of dispersal of radioactive waste or fisheries investigations. Cable measurements are of particular value in such studies as they provide, at minimal cost, a continuous long-term record of the integrated flow across a particular section⁶. However, in recent years many of these cables have either been abandoned or replaced by 'repeated' cables. In the latter, power is fed along the cables to amplify the communications signal at repeated intervals and this tends to distort the measurement of the flow-induced voltage⁷.

Unexpected results found from recording on cables crossing the Pentland Firth (Fig. 1) are particularly interesting. Two cables, running along closely parallel paths, link the Orkneys with the Scottish mainland. Recordings of voltage were made on these cables from February to October 1976, coinciding with the JONSDAP '76 oceanographic exercise in the North Sea. The measurements coming respectively from the two cables were very similar so only the results from cable 2 are presented. Tidal analyses of the recordings were made by dividing the data into six discrete sets each lasting 29 d. Despite the high noise level, the analyses produced consistent results for the principal harmonic constituents (Table 1). However, an examination of the propagation of the M_2 tidal constituent shows that the phase of this constituent calculated from the cable data (that is 18° for flow measured positive towards the east) does not accord with the general pattern of flow as deduced from other data sources (Fig. 1).

Values for the phase of the M_2 constituent of surface currents were calculated from the Admiralty Tidal Stream Atlas. Figure 1 shows values of 271° and 256° obtained for positions in the Firth and a value of 235° at a position slightly east of the Firth. As part of JONSDAP '76 current meter measurements were made at position 53 (58°37' N, 2°25' W). Tidal analyses of these measurements produced an M_2 value of 302° for flow along the major axis of the ellipse aligned 10°W of S. The phase of the vertical tide in this region is indicated by the co-phase lines in Fig. 1 and also by the values from the coastal gauges. Over the region in which the phase of the currents varies from 271° to 302°, the phase of the vertical tide varies from about 250° to

Table 1 Tidal analyses of voltages recorded on the Pentland Firth telephone cable

320°. Thus maximum flows apparently occur within 1 h of tidal high water throughout this region. Therefore the anticipated M_2 phase for flow across the cable section would be in the range 280°–340° compared with the recorded value of 18°.

An examination of the non-tidal (or residual) component from the cable signal shows a reasonable correlation ($r = 0.71$) between the easterly flows through the Pentland Firth and the southerly flows measured by current meters at the nearby position 53. There was no indication of either a significant wind-driven component or a seasonally varying flow component in the residual signal.

Fig. 1 Propagation of the M_2 tidal constituent in the region of the Pentland Firth. ●, Tidal elevation data in cm; ×, tidal stream data in cm s^{-1} (from Admiralty Tidal Stream Atlas); ⊗, current meter data from JONSDAP '76; co-phase lines shown dotted.

One explanation for the anomalous M_2 phase follows from the work of Robinson⁸ who showed that cables respond in a complex fashion to flow over a wide area surrounding the termination points of the cable. He also showed that non-uniformity in sea-bed conductivity can complicate the general integral. In this region, the variability in both the coastline and the tidal stream patterns tends to invalidate the application of simplified formulae of the kind derived by Longuet-Higgins. In addition, the northerly latitude and part east-west alignment of the cable increase the noise level on the cable⁹. The question also arose as to whether any error had been introduced either in the instrumentation or in the data processing.

To establish the validity of these results the recordings were repeated over a 3-month period, July–September 1978. One of the cables had been severed in the interim period and so measurements could only be made on cable 2. To avoid repeating possible errors from the earlier experiment, the recording equipment was installed by a scientist not involved in the earlier recordings. Also, the programmes used to convert the original data into hourly values for subsequent analyses were rewritten. The data were sub-divided into three discrete sets, each of 29 d

duration, for the purpose of tidal analyses. The results, shown in Table 1, closely agree with the values obtained from the 1976 recordings. Thus the voltage recordings from the Pentland Firth submarine cables seem to provide a useful indication of residual flow through the channel but produce an anomalous M_2 tidal signal.

R. I. R. Palin and A. J. Harrison were responsible for the instrumentation and data collection, their assistance in data translation also contributed significantly to this study. This work was funded by a Consortium consisting of the NERC, the Ministry of Agriculture Fisheries and food, and the Departments of Energy, and Industry.

A simple approach for identifying and measuring acidification of freshwater

ACIDIFICATION of lakes and rivers accompanied by the loss of fish populations is a problem in Scandinavia^{1–4}, northeastern USA^{5,6}, and southeastern Ontario, Canada^{7,8}. These areas have granitic or other siliceous bedrock types, thin and patchy podsollic soils, and extremely soft and poorly buffered surface waters, and receive precipitation which is decidedly acidic (volume-weighted average pH 4.0–4.6). Sulphate, whose principal source is precipitation, is usually the major anion in these acidified waters. In similar areas such as northern Scandinavia and northwestern Ontario, in which precipitation is not acidic (pH > 5.0) such oligotrophic pristine softwaters generally have pH levels > 5.5, and bicarbonate is the major anion^{9–11}. Acidification of such waters entails a decrease in the bicarbonate buffer (alkalinity) with only minor decreases in pH, and then after exhaustion of the bicarbonate an increase in acidity to pH levels well below 5.0. Because of the severe damage to fish populations, and other biological consequences, the decreases in pH that characterise the later stages of the acidification process are of major concern. We need, therefore, a simple 'early warning' indicator that identifies lakes and rivers which are undergoing the first stage of acidification, the loss of alkalinity, but which have not yet reached the stage of marked pH decreases. Furthermore, we need quantitative estimates of the degree of acidification. We show here that excess sulphate concentrations, or current calcium concentrations and alkalinity can provide such an estimate.

If bicarbonate is still present, simply measuring alkalinity will not reveal whether or not acidification has occurred unless pre-acidification alkalinity data are available for comparison. Unfortunately, few such data exist. However, in unacidified waters bicarbonate alkalinity is present in approximately equivalent concentrations as the sum of calcium and magnesium (less that of sea-spray origin). As the ratio Ca/Mg is also relatively constant, and pH is closely related to alkalinity and acidity, plots of pH and calcium should distinguish between

Fig. 1 pH and calcium concentrations in lakes in northern and northwestern Norway sampled as part of the regional survey of 1975, in lakes in northwestern Norway sampled in 1977 (○) and in lakes in southernmost and southeastern Norway sampled in 1974 (●). Southern Norway receives highly acid precipitation (pH 4.2–4.5) and a large number of lakes have lost their fish populations due to high acidity^{2,4}. Inset shows areas in which these lakes are located. Areas south of isoline receive precipitation more acid than pH 4.6.

acidified and unacidified waters. This is the case for small Norwegian lakes sampled in 1975 and 1977: most of the lakes in northern and northwestern Norway fall below an empirically drawn curve, whereas lakes in southernmost and southeastern Norway lie above this curve (Fig. 1).

The curve also separates lakes on the west coast of Sweden where pH in precipitation is 4.2–4.4 from lakes in west-central Sweden (W. Dickson, personal communication) where pH in precipitation is less acid (Fig. 2). Furthermore, it also works for North America. Lakes in the Experimental Lakes Area (ELA)¹¹, northwestern Ontario¹¹, and in the Sierra Nevada, California¹² (Fig. 3), areas not receiving highly acidic precipitation, fall below the curve, whereas waters in acidified areas such as the Adirondack Mountains, New York⁶, Hubbard Brook, New Hampshire¹³, and Sudbury, Ontario⁷, fall above the curve.

Figures 1–3 clearly show that the empirical curve distinguishes between lakes situated in non-acidified and acidified areas in Scandinavia and North America. This acidification indicator is particularly useful in that it identifies lakes that have lost some alkalinity but in which pH levels are still high enough for fish populations and other components of the biota to be apparently intact and normal; these waters may be threatened by future inputs of acid components. Thus an 'early warning' is given.

This indicator depends on the observation that in oligotrophic pristine freshwaters calcium is accompanied by a proportional amount of bicarbonate. In such areas, one finds waters in which this is not the case, for example waters containing high concentrations of natural organic acids (highly coloured waters), or waters in areas where the geological environment is such that calcium and bicarbonate are not the major cation and anion, respectively. When applied to data from such waters, the indicator implies an apparent acidification where none has occurred.

The acidification of a lake is the loss in alkalinity that has taken place in the lake water. To quantify acidification we thus need to know the pre-acidification alkalinity and the present-day alkalinity (or acidity in case of acid lakes):

$$\text{Acidification} = \text{pre-acidification alkalinity} \\ - \text{present day alkalinity.}$$

As few historical alkalinity values are available for lakes that are acidified today, an estimate of the pre-acidification alkalinity is therefore needed. Present-day calcium concentrations can be used to estimate alkalinity because in regions not receiving acid precipitation softwater oligotrophic waters contain proportional concentrations of calcium and alkalinity. For example, calcium and alkalinity data from 59 lakes in northern and northwestern Norway gave a least-squares linear regression alkalinity ($\mu\text{Eq l}^{-1}$) = $-29 + 1.32 \text{ Ca}$ ($\mu\text{Eq l}^{-1}$), $r = 0.92$. Similarly, data from 98 lakes in the ELA¹¹ gave alkalinity ($\mu\text{Eq l}^{-1}$) = $-32 + 1.42 \text{ Ca}$ ($\mu\text{Eq l}^{-1}$), $r = 0.87$. (If alkalinity is determined by the standard acidimetric titration to pH 4.5, actual bicarbonate concentrations are overestimated by $32 \mu\text{Eq l}^{-1}$, the amount of free H^+ -ion in solution at pH 4.5. For these regressions the alkalinity data obtained by titration were corrected for this $32 \mu\text{Eq l}^{-1}$.)

These data suggest that the relationship between calcium and alkalinity in pristine softwater lakes is of a general nature. Thus pre-acidification alkalinities can be estimated from present calcium concentrations.

One factor must, however, be considered when estimating pre-acidification alkalinities from present-day calcium concentrations. There is evidence for an increase in the calcium concentrations in acidified areas due to increased chemical weathering and washout from the soil^{10,14,15}. Thus present-day calcium concentrations might overestimate the pre-acidification alkalinity. On the other hand, an increased washout of calcium from a lake catchment probably also results in an equivalent amount of alkalinity which is consumed during the acidification process.

Fig. 2 pH and calcium concentration in lakes in southern (●) and west-central Sweden (○) (data from W. Dickson). Inset shows locations of lakes sampled. Areas south of isoline receive precipitation more acid than pH 4.6.

Fig. 3 Average pH and calcium concentrations in 170 lakes in the Sierra Nevada, California¹² (○), 109 lakes in the Experimental Lakes Area, northwestern Ontario¹¹ (×), 178 lakes in the vicinity of Sudbury, Ontario⁷ (⊙), 216 lakes in the Adirondack Mountains, New York (●) (Schofield, personal communication), and average for 11 yr at Hubbard Brook, New Hampshire¹³ (Δ). Waters in areas receiving acid precipitation lie well above the solid curve, whereas those in other areas lie below. Inset shows locations of these areas. Areas east of the isoline receive precipitation more acid than pH 4.6.

Regional surveys of lakes in southern Norway have been conducted annually since 1974 (ref. 16). Strong acid concentrations using the Gran technique¹⁷ were measured in the 1978 samples, and when combined with pH, calcium and sulphate data, estimation of the degree of acidification can be made for 46 lakes. The acidification estimated this way is closely related to the weighted average concentration of H^+ and sulphate in precipitation at each lake (Fig. 4a, b). These data indicate that significant acidification has occurred in areas receiving precipitation with volume-weighted average concentrations of H^+ above about $20\text{--}25\ \mu\text{Eq l}^{-1}$ (pH 4.7–4.6) and SO_4 concentrations above $1\ \text{mg l}^{-1}$ ($20\ \mu\text{Eq l}^{-1}$). This 'threshold' pH level of 4.6–4.7 was also determined by Wright¹⁸ in an analysis of historical pH data from 217 lakes in southern Norway and Sweden. Lakes in which pH had declined significantly during the past 20–25 yr are located exclusively in areas receiving precipitation more acid than about pH 4.6.

The estimated acidification of lakes in southern Norway is also strongly related to the concentrations of excess sulphate in the lake water, that is, sulphate in excess of that of marine origin as measured by chloride concentrations and the $SO_4:Cl$ ratio in seawater (Fig. 4c). This suggests that the bicarbonate lost in acidified lakes has been replaced by an equivalent amount of sulphate. The excess sulphate concentration in lakes less a 'general Northern Hemisphere' concentration then provides another measure of the acidification. Figure 4a, b indicates that about $10\text{--}20\ \mu\text{Eq l}^{-1}$ ($0.5\text{--}1.0\ \text{mg SO}_4\ \text{l}^{-1}$) is a reasonable estimate of the natural background concentration for lakes in southern Norway. Almer *et al.*¹⁰ suggest $20\text{--}60\ \mu\text{Eq l}^{-1}$ as a general background for Sweden.

Fig. 4 Estimated acidification in 46 lakes in south Norway versus H^+ -concentration (a) and excess sulphate (b) in precipitation at each lake. Precipitation data were interpolated from data given by Dovland *et al.*¹⁹. c, Estimated acidification versus excess sulphate concentrations in 46 lakes. Least squares regression line: $y = -12 + 0.89x$ ($r = 0.99$).

Thus, in areas in which very little sulphur is supplied by weathering and where the ratio of non-marine calcium to magnesium is fairly constant, acidification of freshwaters can be estimated from either present-day excess sulphate concentrations or by present-day calcium concentrations and alkalinity.

I thank W. Dickson and C. L. Schofield for kindly supplying unpublished data.

Palaeogene komatiites from Gorgona Island

UNMETAMORPHOSED mafic and ultramafic rocks overlain by Neogene oceanic sediments are exposed on Gorgona Island which is a remnant of the Coastal Cordillera along the Pacific margin of Colombia¹. Gorgona is one of the rare places in the world where young pyroxenitic komatiites exhibiting typical quenched spinifex textures (Fig. 1) occur. The spinifex rocks form lenticular bodies (? lava flows) within cumulate ultramafics and troctolitic gabbros and are closely associated with diabases and tholeiitic pillow basalts¹. We show here that in textures, rock and mineral chemistry, the Gorgona spinifex rocks are almost identical with the Archean peridotitic to pyroxenitic komatiites from Munro Township (North-east Ontario)². For this reason the term komatiites is used for the Palaeogene rocks, although one could call them high Mg-tholeiites.

Mineral composition: quenched coarse olivine blades up to 5 cm long and 1 mm thick dominate the spinifex texture. The blades are Fo_{90–91} with narrow edges of Fo_{85–86}. Clinopyroxenes and plagioclases are restricted to the interstitial groundmass (Fig. 1). High-aluminium calcic pyroxenes exhibit coarse skeletal crystals; whereas low-aluminium calcic pyroxenes, unzoned plagioclase laths (An_{75–81}) and devitrified and chloritised glass form fine-grained, arborescent crystal aggregates. Chromite occurs mostly in idiomorphic grains.

Fig. 1 Photomicrograph of the spinifex-textured komatiite from Gorgona Island. Weakly serpentinised skeletal plates of olivine are randomly scattered around a groundmass consisting of quenched clinopyroxene aggregates, few plagioclases and devitrified glass.

Rock composition: the major and trace elements have been mainly determined by X-ray fluorescence methods³, the rare earth elements by instrumental neutron activation analysis (INAA in Karlsruhe) (see Table 1).

Outstanding chemical features of these rocks are the high MgO, chromium and nickel contents relative to ocean floor basalts. The olivine compositions seem to be compatible with crystallisation from a liquid with magnesium-values corresponding to the bulk rock composition, giving K_D values (ol/rock)⁴ of about 0.3. We think that the unusual chemical

$$\begin{aligned} \text{Mg-value:} & \quad \text{FeO:Fe}_2\text{O}_3 = 9:1 \\ \frac{100 \text{ Mg}}{\text{Mg} + \text{Fe}^{++}} &= 77.6 \\ &= 74.2 \end{aligned} \quad K_D = \frac{X_{\text{FeO}}^{\text{ol}} X_{\text{MgO}}^{\text{rock}}}{X_{\text{FeO}}^{\text{rock}} X_{\text{MgO}}^{\text{ol}}}$$

composition of these rapidly chilled extrusive rocks within the close neighbourhood of oceanic crust throws new light on the petrological models of generation of ocean floor basalts; by far the most common rock type on Earth. There are several possibilities for the origin of ocean floor basalts: do they represent relatively unmodified primary magmas produced by partial melting from a lherzolite type source rock⁴, did they originate from other ultramafic mantle material followed by crystal fractionation⁵ or could magma mixing of mantle-derived primary magmas together with highly evolved differentiation products along with crystal fractionation have played an important part^{6,7}?

We believe that the Gorgona komatiites represent the least modified liquid generated by partial melting of the upper mantle. They have certain chemical characteristics similar to the melt inclusions in olivine and plagioclase from Mid-Atlantic ridge basalts⁷ (DSDP, Legs 45 and 46, Sites 395 and 396). These include low TiO₂ and Na₂O contents, and high magnesium-values. However, the Gorgona komatiites have higher MgO and nickel contents and are closer to the primary magma, proposed on the basis of experimental evidence⁶, than are the most 'primitive' ocean-floor basalts described to date. Green *et al.*'s primary magma which could have segregated from residual harzburgite at ~20 kbar, 1,430 °C, was experimentally derived from basalt glass (south Mid-Atlantic Ridge, DSDP Leg 3, Site 18, sample 3-18-7-1)⁸ which contains microphenocrysts of olivine (Fo_{89.5}) and plagioclase (An₇₉). This glass also shows very similar rare earth patterns to the Gorgona komatiites. Both are strongly depleted in light rare-earth elements and have low concentrations of large-ion lithophile elements. These aspects will be discussed in more detail elsewhere⁹. Geochemical investigations of the surrounding mafic rocks¹⁰ show that Gorgona Island consists mainly of normal fractionated olivine tholeiites, diabases, troctolites and gabbros, which could be explained by the existence of a shallow magma chamber^{6,7}. The question still remains of whether Gorgona Island represents an uplifted part of a large Pacific oceanic crust or a smaller marginal basin.

Gametogenesis and calcification of planktonic Foraminifera

THE processes of gametogenesis and development in benthic Foraminifera are well known^{1,2}; however, only recently has there been substantial success in the culture of planktonic species³. As part of an investigation of planktonic life cycles, we have maintained in laboratory culture mature foraminifers of *Hastigerina pelagica* and *Orbulina universa* for up to 68 d with more than 80% of the individuals producing gametes. Juvenile stages were subsequently cultured up to initial calcification and regular chamber formation. Although other workers^{4–6} have cultured adults and induced gametogenesis, this is the first known success in the maintenance of gametes and the culture of second generation Foraminifera.

Live, adult, planktonic foraminifers were obtained from pelagic waters off Bermuda by hand capture according to a technique of Bé *et al.*³. Although this method limits specimens to those visible to a diver in 3–20 m of water, it yields healthy individuals undamaged by net tows or conventional samplers. Each organism was isolated in 500–700 ml of filtered natural seawater and aerated lightly. Normal ambient temperatures (19–23 °C) and lighting (12 h, 40–50 foot candles, fluorescent source) were used. To maintain axenic cultures, the seawater was filtered through successive 0.45-µm and 0.1-µm Millipore filters before the introduction of the foraminifers and repeated periodically to remove accumulated by-products. Adult specimens were removed to separate Petri dishes for biweekly feedings of *Thalassiosira fluviatilis* and nauplii of *Artemia* sp. grown in sterile conditions. *H. pelagica* readily accepted both, suggesting that it is an indiscriminate omnivore in nature. *O. universa* did not accept crustaceans, although carnivorous diets have been reported for it as well as for other spinose species^{1,3,5,7}. In any case, our results indicate that planktonic Foraminifera can be maintained readily on an exclusively carnivorous diet although healthiest individuals result from a combined diet of phytoplankton and live Crustacea.

Based on observations of 29 *H. pelagica* and two *O. universa*, gametogenesis can be said to be a predictable development

preceded by several characteristic morphological changes. Between 24 and 36 h before gamete release, the normally expanded calymma decreases until no bubbles or only a single bubble layer is visible around the chambers. Simultaneously, all pseudopodial filaments are retracted into the calcareous test and the main body of cytoplasm constricts into the inner chambers until the last and typically largest chamber is evacuated. The cytoplasm progressively darkens from pale orange or tan to deep orange or golden brown. Previous workers have attributed intense orange-red hues to redistributed lipid storage products⁶; however, in our specimens, orange pigmentation is a dietary phenomenon. While cytoplasmic coloration intensified in all specimens, only those fed high proportions of *Artemia* were deep orange. Others fed exclusively *Thalassiosira* tended to brown and, in one case of gametogenesis within 5 d of capture, to dark grey or black. The latter coloration may be due to local pelagic species of Crustacea in Bermuda, including the copepods *Candacia ethiopica*, *Euchaeta marina* and *Harpacticus* sp., which have black pigments and are sufficiently large to be a feasible food source for these foraminifers.

In *O. universa*, cytoplasmic regression and loss of the calymma coincided with a loss of all major spines. In contrast, in

Fig. 1 Light micrographs of major gametogenic stages of *H. pelagica*. Scale bars, 25 µm. *a*, Onset of explosive release. Gametes and cellular residue are emitted only from major apertures and are densest near remains of terminal chamber. *b*, Masses of gametes flowing along spines in cytoplasmic strands during early to middle stages of gradual release. A few remnants of the parent bubble capsule are evident. *c*, Gamete clumps encased in hyaline material on spines near aperture. Unoccupied spines are dissolving inside a sheath formed by the parent organism. *d*, Terminal stages 10–12 h after release began. Few gametes remain in vicinity of parent test; most spines are resorbed leaving only membrane sheath or base.

no *H. pelagica* were all spines shed and the degree of spine loss or disintegration varied between individuals; remaining spines occasionally served to transport gametes to the periphery (Figs 1*b*, 3*b*). Spines in *H. pelagica* may be lost by resorption of their external bases⁵, by release of the spine from its base, or by progressive disintegration of the spine from its peripheral end (Fig. 1*c*). In five *H. pelagica*, spines began disintegration after onset of gamete release and were effectively dissolved in 4–6 h. The process is assumed to be autolytic because surface seawater is supersaturated in CaCO₃ and would not induce rapid dissolution. Most spines were encased in a residual, membraneous sheath which, as the spine disintegrated, thinned, curving at the peripheral end. More fibril spines were often held in place by secondary mucoid strands. Experiments now in progress

Fig. 2 *a*, Glutaraldehyde-fixed adult at 8-h stage of gamete release. Remains of organelles and developing gametes are found near lip of major aperture. *b*, Post-gametogenic test left 3 weeks in culture. Spines show dissolution pattern. *c*, Biflagellated gamete of *H. pelagica*, fixed 12–15 h after release. The flagella measure 7–10 μm and 12–15 μm respectively. *d*, Initial chamber (proloculus) formed 28 h after gamete release.

indicate that patterns of disintegration within the sheath resemble those of empty foraminiferan tests; however, the triradial spines of vacated tests require up to 6 weeks to produce the same degree of etching as can be produced in 4 h in a gametogenic individual (Fig. 2*b*). The fragility of *Hastigerina* tests was noted by Berger⁸ and a similar spicule dissolution phenomenon shown for other pelagic protozoans⁹. These factors along with limited latitudinal distribution, may explain the relative scarcity of *Hastigerina* in marine sediments.

The actual release of gametes may be explosive or gradual and occurs 2–3 h after the test surface becomes rugose and the cytoplasm dense and granular. In dehiscence, cytoplasm fills the final chambers and gametes are discharged with protoplasm.

Fig. 3 *a*, Syngamy found in culture water 36 h after release, and *b*, on spines of parent test. A pair in which the process is nearly complete can be seen at top centre of *a*. Scale bar, 5 μm . *c*, Three-chambered *H. pelagica* produced in culture within 15 d of gametogenesis. Chambers shown range 27–40 μm in diameter.

The final chamber, formed 4–10 d before the onset of gametogenesis in 20% of our cultures, is lost entirely or part of its outer wall destroyed by forcible expulsion of its contents (Fig. 2*a*). Cytoplasmic residue is later released in a characteristic, streaming pattern (Fig. 1*a*), as reported for *Globigerinella aequilateralis*⁵, and closely resembling phases described for *Elphidium crispum*¹. In gradual release, intensification of the cytoplasm is followed by gametes being extruded along the spines. In spite of rapid flagellar movement, the gametes are normally held in a line by a mucoid coat similar to that covering dissolving spines (Fig. 1*b*). Substantial clumps form at the spine tips within 2 h of the onset of release (Fig. 1*c*) and the flow may continue for 8–10 h. Most gametes, however, reach the periphery and separate from the clumps within 3 h. At this stage, the gametes are dark, ovoid bodies, 2–5 μm long, and have two distinct, unequal flagella with a common base (Fig. 2*c*). The gametes can move just after release although rapid motion does not begin until they are 50–100 μm from the surface of the parent test. Movement is typically a stationary oscillation with rapid flagellar beating or rotation as though due to spinning flagella. Flagellar movement was too rapid to be clearly discerned during swimming. Mobile flagellated gametes survived in culture up to 12 d although most of them calcified or died within 5 d.

Syngamy was rare, observed among gametes of only four *H. pelagica*. No single parameter was common to the cultures in which copulation took place, nor were there apparent morphological differences from other gametes. An estimated maximum of 10% of the population formed syngamous pairs, and frequency of copulation was not increased by combining gametes from two specimens reproducing within the same 36 h. The pattern of copulation was invariable, one gamete remaining relatively still while a second moved rapidly around its periphery, periodically withdrew 10–15 μm , and then forcibly pushed against it. Contact generally occurred between the antilflagellar ends of the gametes with adherence evident at the point of impact (Fig. 3). While thus attached, the two pairs of flagella straightened and beat rapidly, and the gamete pair whirled in the water. The more mobile of the two then broke off, withdrew, and repeated the battering process. Separation became progressively more difficult due to coalescence. This activity continued up to 30 min, ending in a single perceptible organism, about 5 μm in diameter, with two pairs of inactive flagella (Fig. 3*a*). Nuclear material could not be resolved in the living material, but a transfer or fusion is assumed.

Calcification to a single chamber, presumed a proloculus, took place as soon as 9 h after gamete release although most cultures did not show calcification for several days. Single-chambered organisms thus formed were smooth spheres, 8–20 μm across, with few or no apertures perceptible (Fig. 2*d*). The degree of calcification varied, with some individuals forming overlapping layers; however, that may have been a culture abnormality. In only one of our cultures have we found chamber formation beyond prolocula. Two polythalamous individuals were produced (Fig. 3*c*), each forming four chambers within 15 d of gametogenesis, the last chamber appearing within 2 d of the third. The organisms measured 65–80 μm in diameter with the largest chambers 35 and 40 μm in diameter. Both were planispiral with irregularly arranged pores about 1 μm wide and a single 10- μm aperture in the final chamber. No spines have been produced on either individual. None of our second generation specimens has matured beyond this stage and the main difficulties foreseen in further culturing are the provision of appropriate food sources and the formation of culture aberrants with a small sample size.

This work was supported by an ONR contract and facilities of the Bermuda Biological Station. We thank L. Madin for cooperation, Drs Bé and Spindler for advice on culturing and K. Jones for assistance with SEM.

Carcinogenicity testing of herbicide 2,4,5-trichlorophenoxyethanol containing dioxin and of pure dioxin in Swiss mice

SERIOUS environmental contamination is a hazard in the use of derivatives of 2,4,5-trichlorophenol (TCP) as weedkillers¹ or defoliants² and in accidents during the manufacture of TCP³ (as in Seveso, Italy in 1976⁴⁻⁶). 2,3,7,8-Tetrachlorodibenzo-*p*-dioxin (TCDD or dioxin) is an inevitable toxic⁷ teratogenic⁸ and weakly mutagenic^{9,10} by-product which is always present as a contaminant. When TCP derivatives, including 2,4,5-trichlorophenoxyacetic acid (2,4,5-T), were tested for carcinogenicity in (C57BL/6 × C3H/An)F₁ and (C57BL/6 × AKR)F₁ mice (experiments lasting 18 months) none increased tumour incidence¹¹, while in another study there was a significant increase in the incidence of tumours in C3Hf mice treated with 2,4,5-T¹². During a chronic toxicity study with TCDD (a potent inducer of microsomal enzymes¹³) in Sprague-Dawley rats some tumours were observed¹⁴. In another 2-yr study TCDD ingested at 0.1 µg per kg body weight per day caused an increased incidence of hepatocellular and squamous carcinomas in

Sprague-Dawley rats, but reduced the incidence of some other tumours. Smaller doses of dioxin did not affect tumour incidence¹⁵. We report here that both 2,4,5-trichlorophenoxyethanol (TCPE), a derivative of TCP, and dioxin enhance liver tumours in male mice in a dose-dependent manner. Amyloidosis is a long term complication often associated with severe skin lesions induced by TCDD.

Because TCPE is almost insoluble in water it was suspended in a salt solution containing 0.5% carboxymethylcellulose. Dioxin was dissolved in sunflower oil and determined by gas chromatography. Various doses of a combination of TCPE and dioxin, of pure dioxin and of vehicles alone were administered (Table 1). In group 1, TCPE contained 0.3% of contaminants. Ten-week-old, outbred Swiss/H/Riop mice (25-30 g) were used in groups of 100 males plus 100 females, except for groups administered pure dioxin and sunflower oil alone, each of which consisted of 45 males only. Animals were kept in plastic cages at 25 ± 2 °C. Standard diet and water were provided *ad lib*. TCPE contaminated with dioxin, pure dioxin or vehicle alone were administered by gastric tube once a week for 1 yr.

Animals were followed up for the rest of their lives. Autopsies were performed after spontaneous death or when the mice were moribund, and all organs were examined histologically. For light microscopy, sections were stained with haematoxylin and eosin. Amyloid deposits were identified with Congo red stain under polarised light¹⁶ and by electron microscopy. Pathological findings were assessed and analysed statistically. The effective number of animals was the number of survivors at the time the first tumour was observed. Significance was calculated by the χ^2 test. A difference in tumour frequency between groups was considered significant only when *P* was less than 1%. The carcinogenesis study was carried out in three phases (groups 1-3, 4-8 and 9-12) and comparisons were made with the respective control groups.

The LD₅₀ of an acute, peroral dose of TCPE containing 0.1 p.p.m. dioxin is 1,320 mg kg⁻¹. The largest dose of TCPE that induced no noticeable tissue lesions in the organs of the mice during 6 months of administration was 70 mg per kg. That was therefore taken as the maximum tolerated dose.

Table 2 Occurrence of amyloidosis with skin lesions induced in mice by dioxin

Groups	Treatment		Effective no. of mice	Skin lesion no.	Skin lesion + amyloidosis no.
	Dioxin ($\mu\text{g per kg}$)	Vehicle (mg per kg)			
9	7.0	10.0	43	25	17
10	0.7	10.0	44	13	10
11	0.007	10.0	44	5	5
12	—	10.0	38	0	0

The cumulative data in Table 1 show that only the incidence of liver tumours of the males significantly differed between groups. Subsequent comparisons therefore relate to the males. The incidence of liver tumours in groups 1, 2 and 10 was twice that in the respective controls (groups 3 and 12). The smaller doses of TCPE and dioxin given to groups 5 and 6 (1/10 and 1/100 of maximum tolerated dose) caused less frequent tumours; there were no significant differences from groups 7 and 8. There were no significant differences in the frequency of liver tumours between groups 1 and 2 (given dioxin at 0.112 and 0.007 $\mu\text{g per kg}$) or groups 4 and 5. The latter two groups received equal amounts of TCPE but group 4 received 100 times more dioxin than did group 5. Thus, dioxin in this dose range did not influence tumour frequency.

Groups 11 and 2 received equal amounts of dioxin (0.007 $\mu\text{g per kg}$) but there was no significant difference in liver tumour incidence between group 11 and its control, group 12. Thus dioxin has no liver tumour enhancing effect at this dose. The increased incidence of liver tumours in group 2 was caused by TCPE and not by dioxin. In group 10, which received 100 times more dioxin than did group 11 (0.7 $\mu\text{g per kg}$), liver tumour incidence was twice that in the control, group 12. Thus dioxin has a liver tumour enhancing effect at a higher dose. Dioxin contamination in group 4 was less than 0.7 $\mu\text{g per kg}$ —the threshold dose of TCDD in our experiment—and its hepatocarcinogenic effect could not be observed.

Spontaneous and induced liver tumours were not histologically different. The ratio of benign hepatomas to hepatocellular carcinomas in the control groups was not affected by treatment; only the absolute number of liver tumours increased. No cirrhosis was seen concurrently with tumours.

Average life span decreased considerably in group 9 (Table 1) which received the largest dose of TCDD. TCDD caused severe chronic, ulcerous skin lesions (probably similar to chloracne in humans) followed by generalised lethal amyloidosis (Table 2), which can be regarded as a process secondary to chronic skin lesion¹⁷. This group was not evaluated in the carcinogenic bioassay for early death.

Until more is known about the people who have been exposed to them, the carcinogenicity of 2,4,5-T and structurally related chemicals in humans cannot be evaluated¹⁸⁻²¹. But it is clear that not only dioxin contamination, but also exposure to TCPE during its production or use should be controlled and reduced. Amyloidosis should be considered a possible later complication of the most severe forms of human chloracne induced by TCDD.

A preliminary report of this study was presented at the International Conference on Ecological Perspectives on Carcinogens and Cancer Control in Cremona in 1977²². This work was initiated by the late Professor B. Kellner. We thank Mrs Rose Gaál Szabo for technical assistance.

Initiation of development of diapausing embryo by mammary denervation during lactation in a marsupial

MOST macropodid marsupials conceive at postpartum oestrus and the 100-cell embryo enters into and remains in embryonic diapause while there is a suckling young in the pouch¹. Removal of the pouch young results in reactivation of the quiescent corpus luteum and of the diapausing blastocyst. Prolactin inhibits corpus luteum development tonically during lactational quiescence in the tamar wallaby, *Macropus eugenii*². However, it is not known whether the hormonal milieu associated with lactation, or the neural stimulus of suckling itself is the primary signal to the hypothalamus which results in the maintenance of embryonic diapause in *M. eugenii*. I therefore examined the role of the neural pathway from the mammary gland in tamar wallabies carrying diapausing embryos. I report here that after denervation of the suckled mammary gland, the quiescent corpus luteum and the diapausing blastocyst resumed development, whereas none of a sham-operated group initiated blastocyst development. The pouch young grew at a normal rate and continued to obtain milk from denervated glands, despite the presence of a developing embryo in the uterus.

Only one of the four available teats is suckled by a particular pouch young. Each teat has a separate mammary gland, but the anterior and posterior teats on each side are less than 1 cm apart³. In experimental animals, the suckled gland and its ipsilateral partner where chosen for denervation, whereas, because of the diffuse nature of the innervation, in control animals the contralateral pair were denervated.

Denervation was effected by cutting around the chosen pair of nipples, and clearing the gland from the connective tissue until the ilio marsupialis muscle, through which the mammary nerves pass, was clearly visible. The minor blood vessels and ducts leading to the mammary lymph glands were ligated, the muscle layer cut through, and the remaining fascia and connective tissue cleared from the entire gland until it was connected only by the intact major artery and vein and there was no sign of any remaining nerves. After repair of the wound the pouch young, aged either 35 or 60 d, was replaced on the nipple.

Pouches were checked daily for the first 7-10 d. Subsequently, the females were replaced in their outdoor enclosures until laparotomy on either day 22 or 23 post-denervation.

After laparotomy, all control and pregnant experimental animals were killed. The corpora lutea were weighed directly, and embryos measured and aged, as previously described^{4,5}.

Table 1 Influence of denervation of the mammary gland on embryonic diapause; status of embryos 22 d after denervation of the suckled (experimental) or non-suckled (control) mammary gland

No. of animals	Pouch young status	Blastocyst or vesicle recovered	Day 22/23 embryos	Developed§ CL or follicle but no embryo	No blastocyst,§ unfertilised egg, CL or follicle	Total activated after operation
Experimental						
9	5 remained on teat	0	3*	1	1	7/9
	4 lost 5-14 d	0	1*	2	1	
Control						
4	3 remained on teat	2†	0	0	1	0/4
	1 lost 9 d	1‡	0	0	0	

Anaesthesia was induced by 2.0 ml sodium pentobarbitone (60 mg ml⁻¹) in 0.9% NaCl, maintained by halothane in oxygen. CL, corpus luteum.

* Embryo sizes (crown-rump length), 10 mm, 14.8 mm, 13.3 mm, 11.1 mm. † Blastocyst sizes (diameter), 0.25 mm, 0.26 mm. ‡ Vesicle size (diameter), 0.6 mm.

§ Three of the five denervated animals which were not pregnant underwent an infertile cycle, and had a developing follicle and enlarged corpus luteum at laparotomy. The remaining two denervated animals and one of the four controls had no apparent postpartum ovulation, as there was no corpus luteum in the ovary, and no egg or blastocyst in the uterus.

Mammary glands were fixed in buffered formalin for histological examination. Non-pregnant experimental animals were examined by laparotomy for post-luteal follicular development or corpora lutea and allowed to recover.

After denervation of the suckled mammary gland, the quiescent corpus luteum resumed development, as indicated by increased size and weight, and post-luteal follicular growth was observed in seven of nine experimental animals (Table 1). In four of nine animals embryos developed despite the presence of a suckling pouch young. Twenty-one days after denervation the embryos of these four fitted within the size range of normal 22-d embryos⁵. The five pouch young which remained on the denervated glands grew normally, and when measured and aged on a growth curve⁶ all had maintained a normal growth rate. Pouch young were lost in four cases. Histological examination of the glands confirmed that the nerve supply remained severed. In the

control group, none of the four animals initiated development, although one which lost its pouch young between 9 and 13 d after the operation carried a 10-d vesicle at laparotomy on day 22 (Table 1). Thus, surgery itself did not cause resumption of development.

These results show that the neural stimulus derived from suckling is essential to maintain the quiescent state of the diapausing blastocyst, but that an intact mammary neural connection is not essential for maintenance of this stage of lactation in this species. Milk secretion after denervation continued apparently unimpaired in five of the nine experimental animals. Histologically, the glands seemed normal when compared with glands obtained from animals carrying pouch young of the same age (60-84 d). However, it is not possible to say whether the remaining four were lost (at days 5, 11, 12 and 14 post-denervation) due to a failure of lactation (such as the absence of oxytocin and the milk ejection reflex), or to post-operative behavioural abnormalities. Milk was observed slowly leaking from the denervated teat before replacement of the pouch young, and in animals which lost their pouch young the gland became swollen. In other species, the myo-epithelium can be induced to contract by rapid mechanical stretching⁷; pouch young could certainly pull the denervated teat during their movements in the pouch and this may counteract the lack of oxytocin release. Oxytocin in *M. eugenii* thus may be a facultative but not obligatory mechanism for effective milk discharge, as Cross⁹ suggests for the goat.

The ability of denervation to allow the corpus luteum to resume growth, and lactation to continue, contrasts with the results of hypophysectomy in this species, in which the corpus luteum also resumes development but lactation and follicular growth fail¹⁰. However, lactation continues after removal of the corpus luteum although follicular development begins and animals return to oestrus 11 d later². It must be concluded that suckling, mediated through the neural pathway and prolactin, inhibits the corpus luteum, and that it is corpus luteum secretions (such as progesterone or oestradiol-17 β) which inhibit subsequent follicular development in the intact animal.

These findings provide evidence for the role of the neural pathway from the mammary gland as a primary signal to the hypothalamus in maintaining embryonic diapause during lactation in a marsupial species. Figure 1 shows how this finding is consistent with present evidence for the control of reproductive activity in this species during lactational quiescence.

John Leonard helped develop the denervation technique, and Professor R. H. Dunlop made useful suggestions. I thank Drs M. Peaker, R. V. Short and R. B. Heap for discussions, and Stuart Green for assistance. Financial support was provided by the NIH (NICHD, HD 09387) and the Australian Research Grants Committee (D1-95/18759).

Fig. 1 An hypothetical scheme showing pathways consistent with present evidence for the control of lactational quiescence in the tamar wallaby. Removal of the pouch young and thereby the suckling stimulus leads to resumption of corpus luteum growth and of embryonic development, with oestrus and ovulation occurring at the end of the 27-d pregnancy¹. Removal of the pituitary leads to resumption of corpus luteum and blastocyst growth¹⁰ but ovulation and follicular development fail¹⁰. Hypophysectomy followed by prolactin injection prevents resumption of corpus luteum development², and bromocriptine administration in intact animals results in reactivation of the corpus luteum¹¹. Removal of the corpus luteum leads to oestrus and ovulation 12 d later², presumably due to the removal of small amounts of steroids derived from the quiescent corpus luteum that may inhibit pituitary gonadotrophin secretion. It is not clear, however, whether such corpus luteum inhibition acts directly on the pituitary, or through the hypothalamus, as suggested elsewhere^{12,13}. CL, corpus luteum; E β , oestradiol-17 β ; F, follicle; FSH, follicle-stimulating hormone; LH, luteinizing hormone; LH-RH, luteinizing hormone releasing hormone; PIF, prolactin inhibiting factor; PRO, prolactin; Prog, progesterone; †, stimulation; ‡, inhibition; +, increased levels; -, decreased levels.

Abelson virus-transformed haematopoietic cell lines with pre-B-cell characteristics

THE Abelson murine leukaemia virus (A-MuLV) complex, which consists of a replication-defective focus-forming virus and its helper Moloney leukaemia virus, causes a thymus-independent lymphosarcoma in BALB/c mice¹. Infection *in vivo* leads to the production of tumours which are usually classified as 'null' lymphoid cells², although immunoglobulin (Ig)-synthesising B-cell lines have been reported³⁻⁵ and macrophage lines may occasionally be produced⁶. In some cases, particularly with pretreatment of the mice with the mineral oil pristane, there is a high incidence of Ig-producing plasmacytomas⁷. Additional data on Ly phenotypes have suggested that most A-MuLV tumours, including those with no demonstrable Ig synthesis, may be B-cell lineage derivatives⁸. Here, we provide evidence for A-MuLV transformation of B-cell precursors resulting in two cell lines which retain the capacity for inducible IgM synthesis. Line ABC-1 was derived from BALB/c mouse bone marrow cells transformed *in vitro* by the Abelson virus⁹ and line ATV-3 from a tumour in a BALB/c mouse inoculated with A-MuLV.

The ABC-1 cells are large, vacuolated, undifferentiated blast cells. Immunofluorescence and cytotoxicity tests indicated that no cells had cell surface immunoglobulin (SmIg) or expressed detectable levels of Thy-1.2, suggesting that there were no mature B or T lymphocytes present. Additional characterisation of this cell line (Table 1) revealed that no cells expressed Ia or TL 1,2,3,4 antigens or peanut agglutinin binding sites (Gal(β1-3)-GalNac), the latter being a marker for thymocytes and T-cell precursors¹⁰. All cells contained cell surface exposed G_{M1} gangliosides as indicated by binding of ¹²⁵I-cholera toxin or fluoresceinated cholera toxin. The cells did not react with a rabbit antiserum specific for antigens on a gp100 molecule associated with a human non-T, non-B or 'null' lymphoblastic leukaemia^{11,12}. Preliminary experiments suggest that the ABC-1 cells, in common with other A-MuLV-transformed lines⁸, have low but detectable levels of terminal deoxynucleotidyl transferase (M.B., unpublished observations).

The use of affinity-purified antibodies to mouse IgM conjugated with fluorescein indicated an absence of cells with detectable cell surface fluorescence, although 1-4% showed cytoplasmic staining. No cytoplasmic fluorescence was seen in controls of AKR leukaemic T lymphocytes and normal thymocytes. In normal spleen, plasma cells stained intensely.

The presence of cytoplasmic IgM in a minor proportion of cells and the absence of staining for surface membrane Ig indicate the presence of cells with the characteristics of the earliest detectable cells in the B-cell lineage, that is, 'pre-B' cells^{13,14}.

We next attempted to induce lymphoid differentiation in ABC-1 cells which had been in continuous culture for only 8 months. Dimethyl sulphoxide (DMSO), 1%, failed to induce any increase in the percentage of cells expressing cytoplasmic

Table 1 Surface membrane phenotype of an *in vitro* Abelson virus-transformed line ABC-1

Marker	% Positive cells		
	A-MuLV line: ABC-1	Controls (BALB/c) Spleen	Thymus
SmIg	<0.01	40	2
Thy-1.2	<1	19	83-95
Ia	<1	30-45	3
TL 1,2,3	<5	<5	11
TL 4	<5	<5	46
Peanut agglutinin	1	3	>95
Cholera toxin receptors	100	100	>95
Fc receptors	25	34	5
Human gp100 cALL antigen	<0.1	ND	<0.1

Surface membrane immunoglobulin (SmIg) was detected by direct immunofluorescence using several anti-Ig antisera, including rabbit anti-mouse Ig (non-class specific) and a rabbit antiserum specific for IgM. Thy-1.2 was determined by indirect immunofluorescence using an AKR anti-CBA thymocyte antiserum (Searle) followed by a fluorescein-labelled rabbit anti-mouse Ig and a two-stage ⁵¹Cr-release cytotoxicity test using the same anti-Thy-1.2 antiserum plus rabbit complement (1:15). Values given refer to results by ⁵¹Cr release and represent the percentage specific lysis. Ia expression was tested by indirect immunofluorescence techniques and a two-stage cytotoxicity test (using trypan blue exclusion). Anti-Ia was a (B10.A × A) anti-B10.D2 antiserum (anti-Ia^d). Values for controls are derived from indirect immunofluorescence experiments in which it was necessary first to remove surface membrane Ig of spleen cells by 'capping'. TL antigens were detected by complement-mediated cytotoxicity. Anti-TL antisera were produced by immunisation of appropriate congenic strains of mice. Anti-TL-4 was raised by immunising (A × C57BL/6-Tla^a) mice with a C57BL thymic lymphoma line (ERLD). Anti-TL 1,2,3 was raised by immunising (A-Tla^a × C57BL/6) with a thymic lymphoma line (ASL1) derived from an A strain mouse. cALL, common acute lymphoblastic leukaemia antigen. ND, not determined.

Table 2 Stimulation of cytoplasmic IgM production in an *in vitro* transformed line ABC-1

Treatment	% cells staining for cytoplasmic IgM on			
	Day 0	Day 1	Day 4	Day 7
None	1-4	1-4	1-4	1-4
<i>Escherichia coli</i> LPS				
5 μg ml ⁻¹	—	20	23	25
20 μg ml ⁻¹	—	25	39	25
Dimethyl sulphoxide, 1%	—	ND	23	4
Butyric acid, 1 mM	—	1	18	4
Pokeweed mitogen conditioned medium	—	7	34	ND

Concentrations of each inducer shown are those which, out of the range of concentrations used, were found to induce maximal stimulation of cytoplasmic IgM-positive cells. Pokeweed mitogen conditioned medium refers to supernatant from syngeneic spleen cell cultures (5 × 10⁶ fresh cells ml⁻¹) incubated for 72 h with pokeweed lectin(s) (15 μg ml⁻¹). The cells were removed by centrifugation (1,300 g) and the conditioned medium used at one part conditioned medium to two parts fresh medium. Abelson virus-transformed cell cultures were set up at 10⁶ cells per ml on day 0 and assayed on days 1, 4 and 7 for the presence of surface membrane Ig and Thy-1.2 by fluorescence techniques (see legend Table 1). Thy-1.2 was also assayed on five occasions by a ⁵¹Cr-release cytotoxicity test. Smears were also made and stained with anti-IgM antibodies (see legend to Fig. 1). Rabbit anti-mouse IgM (μ-chain specific) antiserum was raised by immunisation with purified MOPC 104E myeloma protein (Ig). The rabbit antibodies were isolated on a MOPC 104E-4B Sepharose immunoabsorbent column, passed over mouse myeloma IgG-4B Sepharose to remove anti-γ chain cross-reactivity and conjugated to fluorescein or rhodamine isothiocyanate.

IgM or *de novo* expression of cell surface Ig. Lipopolysaccharide (LPS), at doses of $5\text{--}20\ \mu\text{g ml}^{-1}$, rapidly induced an increased expression of cytoplasmic IgM, maximally 9–10% 2 d after addition (data not shown).

Cells which had been in continuous culture for longer (16 months) showed a more pronounced stimulation of cytoplasmic IgM-positive cells (20–40%). Several compounds were tested for their ability to elicit differentiation; these were added over a range of doses to fresh cultures (Table 2). Cells were assayed on days 1, 4 and 7 for the presence of Thy-1.2, SmIg and cytoplasmic IgM. DMSO, LPS, butyric acid and conditioned medium from BALB/c spleen cell cultures stimulated with pokeweed lectin(s) (PWM), all increased the percentage of cytoplasmic IgM-positive cells. No cell surface Ig-positive cells were detectable after these treatments. Of the compounds tested, only LPS induced an increase in cells with cytoplasmic IgM production within 1 d, but there was no significant difference in proliferation over this period ($8.7 \times 10^5\ \text{ml}^{-1}$ and $9.3 \pm 0.3 \times 10^5\ \text{ml}^{-1}$ for control and LPS-stimulated cells, respectively). Stimulation by butyric acid and PWM conditioned medium was not evident at day 1 but was seen at day 4.

In contrast to the responses elicited by the above compounds, dextran sulphate ($2\text{--}50\ \mu\text{g ml}^{-1}$), concanavalin A ($5\text{--}10\ \mu\text{g ml}^{-1}$), PWM ($5\ \mu\text{g ml}^{-1}$), dibutyl cyclic AMP

($1.25\text{--}5 \times 10^{-4}\ \text{M}$), cholera toxin ($0.01\text{--}1.0\ \mu\text{g ml}^{-1}$), phytohaemagglutinin ($2.5\text{--}20\ \mu\text{g ml}^{-1}$) and purified protein derivative of tuberculin ($5\text{--}50\ \mu\text{g ml}^{-1}$) all failed to stimulate an increase in cells with cytoplasmic IgM, Thy-1.2 or SmIg.

Several cell lines were also isolated from tumours in BALB/c mice which had been injected intraperitoneally at 5–7 d of age with Abelson virus. All these lines were negative for Thy-1.2 and SmIg. We attempted to induce lymphoid differentiation in two lines in which there were no cells showing detectable cytoplasmic fluorescence with anti-IgM; DMSO, dextran sulphate, LPS, thymopoietin, iododeoxyuridine, and interferon ($475\ \text{units ml}^{-1}$) with or without 1% DMSO or dextran sulphate, did not induce expression of Thy-1.2, cell surface Ig or cytoplasmic IgM.

A third line (ATV-3) had 5–22% (mean 15%) cells with cytoplasmic IgM, none of which had detectable cell surface immunoglobulin. After 48–72 h culture with $10\ \mu\text{g ml}^{-1}$ LPS the proportion of cells with cytoplasmic IgM had increased to 35% and 70% in two experiments, with no concomitant appearance of cell surface Ig.

Synthesis of IgM by both ABC-1 and ATV-3 lines was confirmed by SDS-polyacrylamide gel electrophoresis and fluorography (Fig. 1). Both lines apparently synthesised μ heavy chain and light chain.

The synthesis of IgM by these lines and the induction of increased numbers of detectable IgM-containing cells imply that A-MuLV had transformed immature B-lymphoid lineage committed precursors. A minority of cells in both lines seems to have a maturation arrest at the level of 'pre-B' cells whereas a substantial proportion are presumably less mature but can be induced to express pre-B features. No *bona fide* 'mature' B cells (cell surface Ig positive) have been inducible in these lines. It is interesting that LPS and PWM-activated cell supernatants induce pre-B-cell characteristics in ABC-1 cells, whereas concanavalin A, phytohaemagglutinin or pokeweed lectin itself do not, as this parallels the differential mitogenic effects of these same compounds on purified murine T and B cells *in vitro*¹⁵. Previous work has indicated that polyclonal B-cell activators may selectively depress DNA synthesis of A-MuLV-transformed cells¹⁶. LPS has also been reported to stimulate a chemically induced pre-B-cell line to express cell surface Ig¹⁷. These data and analyses of Ly antigen phenotypes⁸ support the view that A-MuLV-transformed cells are predominantly B-lineage committed cells.

Baltimore *et al.* have recently provided further evidence for B-cell differentiation in several A-MuLV-transformed lines^{18,19}, some of which are similar to the two reported here in synthesising μ chains with no cell surface representation¹⁸. These lines apparently synthesised light chains only following stimulation with LPS^{18,19}.

Abelson virus therefore seems to transform mainly B-lineage lymphoid cells. In the two lines reported here in detail, transformation *in vitro* (ABC-1 line) or *in vivo* (ATV-3 line) resulted in the production of lines with features indicative of early maturation compartments in the B-lymphocyte lineage. The availability of such cells with at least a partial competence for reversal of maturation arrest should be useful for studying early molecular events in the control of immunoglobulin gene diversification and expression.

We thank Janice Rowe for technical assistance, Ms J. Riggs for secretarial work, and Dr Baltimore and colleagues for allowing us to read and quote results from their laboratory that are in the press. Anti-Ia antiserum was provided by Drs M. Feldmann and I. McKenzie, and anti-TL antisera by Drs R. Basch and N. Hogg.

Fig. 1 Fluorography of SDS-polyacrylamide gel electrophoresis showing μ heavy and light chain synthesis by Abelson virus-transformed cells (ATV-3). Slot 1, immune precipitate with rabbit anti-mouse μ chain antibodies; slot 2, immune precipitate with normal rabbit serum; slot 3, Coomassie blue-stained tract containing MOPC-104E IgM. Positions of heavy (H) and light (L) chains from MOPC-104E indicated. Molecular weight markers (arrowed) are (from top to bottom): β -galactosidase (135,000); phosphorylase α (94,000); lactoperoxidase (80,000); catalase (60,000); alcohol dehydrogenase subunit (yeast, 37,500) and carbonic anhydrase (29,000). 1×10^6 cells were incubated at 37°C for 16 h with $250\ \mu\text{Ci } ^{35}\text{S}$ -methionine in methionine-free medium. The labelled cells were washed three times in methionine-free medium and extracted in 3 ml 0.01 M Tris, pH 8, 150 mM NaCl and 0.5% NP40 for 15 min at 4°C . The cell extract was centrifuged at $100,000g$ for 1 h at 4°C ; $250\ \mu\text{l}$ were incubated overnight with $20\ \mu\text{l}$ of rabbit anti-mouse μ chain or normal rabbit serum and the immune complexes isolated by *Staphylococcus aureus* precipitation. The bacteria were pelleted, washed three times in the above buffer with 0.25% gelatin, and bound complexes were eluted by boiling in $70\ \mu\text{l}$ of 10% glycerol, 2% SDS, 0.05 M Tris, pH 6.8, plus $10\ \mu\text{l}$ 1 M dithiothreitol in 0.1% bromophenol blue indicator. The eluted complexes as well as the reduced MOPC-104E and marker proteins were subjected to SDS-PAGE.

Retinoic acid inhibition of Epstein-Barr virus induction

TUMOUR promoters of the diterpene type efficiently induce Epstein-Barr virus (EBV) and additional persisting herpes viruses in genome-harboring lymphatic cells^{1,2}. The tumour-promoting activity of these substances to some extent parallels their efficiency in virus induction²: the most active tumour promoters induce EBV even at concentrations of 10^{-10} – 10^{-9} M, whereas 100–500-fold higher concentrations are required for induction by weak promoters. Treatment of cells with tumour promoters results in a fast and reproducible increase in the activity of ornithine decarboxylase (ODC)^{3,4} up to 250-fold levels of normal activity. Recent reports^{5,6} described the inhibition of ODC induction by pretreating the cells with retinoic acid. Moreover, retinoic acid has been reported to act as an inhibitor in experimental 2-stage carcinogenesis models⁷. We have therefore investigated the possible interaction of retinoic acid with virus induction by tumour promoters. The effect of retinoic acid was also studied on the induction of early antigens (EA) of EBV by the pyrimidine analogue, iododeoxyuridine (IUdR)^{8,9}, by treatment of IgM-producing cells with anti-IgM antibodies¹⁰ and by superinfection with EBV from P3HR-1 cells^{11,12}. The data indicate that retinoic acid specifically interferes with induction by non-viral reagents without affecting EBV antigen synthesis after superinfection.

cis-Retinoic acid (Nordmark) was dissolved in ethanol diluted in tissue culture medium and applied to Raji cells in concentrations ranging between 10^{-8} and 5×10^{-5} M. No cellular growth inhibition was noted up to 10^{-5} M; at 5×10^{-5} M there was a slight decrease in growth over a period of 5 d.

Concomitant treatment of these cells with 12-*O*-tetradecanoyl-phorbol-13-acetate (TPA) and retinoic acid resulted in effective inhibition of EA induction by TPA (Fig. 1). At 10^{-5} M, more than 90% of EA induction by TPA was suppressed and some inhibition was still obvious at 10^{-6} M. Kenner *et al.*⁶ reported that pretreatment of the cells with retinoic acid 1 h before TPA addition was most effective in inhibiting ODC induction. We therefore carried out analogous experiments, but found no difference in the inhibition of the EA response, regardless of whether the cells were pretreated or simultaneously treated with retinoic acid. Pretreatment of the cells with retinoic acid (10^{-6} M) for 12 h followed by subsequent washing and addition of TPA still resulted in more than 90% inhibition of EA induction. Additional experiments with retinoic acid, using a different tumour promoter (Pimelea factor P2), yielded analogous results to TPA treatment.

We then investigated the specificity of the inhibitory effect of retinoic acid on EBV antigen induction by tumour promoters. Raji cells induced by IUdR or anti-IgM-antiserum to EA synthesis were treated simultaneously with varying concentrations of retinoic acid (Figs 2, 3). Although IUdR induction of EA seems to be less strongly inhibited than TPA induction, some inhibition is obvious over a relatively wide range of retinoic acid concentration. EA induction by anti-IgM is clearly inhibited by retinoic acid.

Further experiments were designed to test the influence of retinoic acid on EA induction by superinfecting Raji cells with EBV derived from P3HR-1 cells^{11,12}. Retinoic acid did not affect the percentage of EA-positive cells, even when applied at 10^{-5} M. Similarly, the spontaneous induction rate of P3HR-1 and B95-8 cells, which is approximately 6 and 4%, respectively, was not significantly altered by applying retinoic acid at 10^{-7} – 10^{-5} M for 3 and 5 d.

These data show that retinoic acid inhibits virus induction by chemical inducers and anti-IgM antiserum without affecting antigen synthesis after superinfection or spontaneous induction. This suggests that the different inducing reagents activate the persisting genomes indirectly by a common mediator which seems to be inhibited by retinoic acid. EA induction by superinfection or spontaneous induction of viral antigens in tissue culture cells apparently follow different pathways. Such observations are consistent with the recent demonstration of a correlation between inducibility by promoters, IUdR and anti-IgM antiserum and EBV genome equivalents per cell (K.B. *et al.* in preparation), whereas the response to superinfection seems to be independent of genome numbers in EBV genome-carrying cells.

Fig. 1 Effect of retinoic acid on induction by TPA in Raji cells (clone no. 7, K.B. *et al.*, in preparation). The cells (5×10^5 per ml) were incubated in 10 ml medium (RPMI 1640 containing 10% fetal calf serum) in the presence of 20 ng ml^{-1} TPA and various concentrations of retinoic acid. The % of EA-positive cells was determined at indicated times by indirect immunofluorescence¹¹. a, The % of EA-positive cells; b, the % of inhibition in the presence of retinoic acid compared with the control cultures (without retinoic acid). O, Day 1; ■, day 3; ▲, day 5; △, day 7.

Fig. 2 Effect of retinoic acid on EA induction by IUdR in Raji cells (clone no. 7): 10 ml of the cells (5×10^5 per ml) were incubated in the presence of $100 \mu\text{g ml}^{-1}$ IUdR and various concentrations of retinoic acid. ■, Day 3; ▲, day 5, △, day 7.

Fig. 3 Effect of retinoic acid on EA induction by anti-IgM antiserum. Raji cells were incubated with 1% of rabbit anti-human IgM antiserum (Behring-Werke) and retinoic acid in conditions outlined in Figs 1 and 2. ■, Day 1; ▲, day 2; □, day 4.

It is uncertain whether the inhibition of ODC activity by retinoic acid has any direct relationship to inhibition of virus induction by retinoic acid. Preliminary data indicate that neither putrescine, which should interact with ODC by feedback inhibition^{13,14}, nor colchicine, which is also reported to inhibit TPA-induced ODC activity¹⁵, reduce the number of TPA-induced Raji cells (H.z.H., unpublished data). This seems to dissociate virus induction from ODC stimulation and stresses the specificity of the virus induction process by diterpene esters.

If herpes virus persistence in general is affected by the application of retinoic acid, this could have important implications for the prevention of recurrent herpetic infections.

Teratocarcinomas rarely develop from embryos transplanted into athymic mice

SEVEN-DAY-OLD mouse embryos transplanted to extra-uterine sites give rise to tumours that have been classified as either benign teratomas or malignant teratocarcinomas¹. The ratio of teratomas to teratocarcinomas varies from one mouse strain to another, suggesting the existence of teratocarcinoma-permissive and nonpermissive strains². Control of teratocarcinogenesis in this tumour system resides in the adult recipient of the embryonic graft and might involve the immune response. We report here that we have tested the hypothesis that the absence of cell-mediated immunity enhances the growth of transplanted embryos and facilitates the development of teratocarcinoma. Contrary to our expectations, our data indicate that embryos grafted into recipients with partial or total deficiency of cell-mediated immunity grow poorly and develop almost exclusively into benign teratomas.

We compared the outgrowth of 7-d-old embryos derived from teratocarcinoma-permissive (C3H/HeJ) and teratocarcinoma-nonpermissive (C57BL/6J) mouse strains. These embryos were transplanted under the kidney capsule of normal syngeneic mice, thymectomised, irradiated and bone marrow-reconstituted (TIR) mice, and athymic (*nu/nu*) mice. Results are summarised in Table 1.

Tumours obtained in the syngeneic recipients were as previously described². In C3H/HeJ mice, two out of three of the

Table 1 Weight of tumours and the ratio of teratomas to teratocarcinomas obtained from 7-d-old embryos transplanted under the kidney capsule of adult recipients

Embryo	Recipient	No of grafts	Weight of tumours (mg±s.e.m.)	Teratoma/teratocarcinoma
C3H	C3H, untreated	94	3,569±330 (a)	33/61 (e)
	C3H, TIR	21	557±117 (b)	17/4 (f)
	Nude, <i>nu/nu</i>	14	814±240 (b)	10/4 (g)
C57BL	C57BL, untreated	71	2,178±279 (c)	64/5 (h)
	Nude, <i>nu/nu</i>	21	538±97 (d)	20/1 (j)

An embryonic portion of 7-d-old embryos was isolated and transplanted under the kidney capsule of adult recipients which were: untreated, 2-month-old C3H/HeJ and C57BL/6J; athymic; thymectomised, irradiated and bone marrow-reconstituted (TIR) mice. Athymic (*nu/nu*) mice were on BALB/c background. TIR animals were thymectomised as weanlings, irradiated 2 weeks after thymectomy with 850 rad and reconstituted with 2×10^7 syngeneic bone marrow cells. Animals that survived and recovered completely were used as recipients 4 weeks after reconstitution. Recipient animals were killed 2 months after grafting. Diagnosis of teratoma and teratocarcinoma was made histologically. *P* value, as calculated by Student's *t* test, was <0.005 for *a* relative to *b*, *c* to *d*, and *a* to *c*. *P* values, as calculated by χ^2 test, were as follows: <0.005 (*e* relative to *f*), <0.025 (*e* to *g*), >0.75 (*f* to *g*), <0.005 (*e* to *h*), >0.1 (*g* to *j*), >0.9 (*h* to *j*).

tumours were teratocarcinomas, whereas in C57BL/6J mice, less than 10% of tumours were classified as teratocarcinomas. The proportion of teratocarcinomas in C3H/HeJ mice was significantly higher than in nude and TIR recipients. In addition, all embryo-derived tumours in nude and TIR recipients were considerably smaller than those in control mice. Tumours as well as the adjacent kidney parenchyma of both nude and TIR animals often contained aggregates of small lymphocytes.

Our results show that the removal or absence of the T-cell immune system in recipients of embryonic grafts not only does not stimulate the development of teratocarcinomas but apparently inhibits teratocarcinogenesis. Two hypotheses could explain these observations. First, in agreement with the immunostimulation theory of Prehn³, one could postulate that an interaction between the transplanted embryo and the T-cell immune system is necessary for teratocarcinogenesis. TIR mice are not completely devoid of T-cell functions⁴, but the number of T cells they have might be insufficient for immunostimulation. The alternate hypothesis is that the development of teratocarcinomas was inhibited by natural killer cells and/or macrophages. Nude mice have high levels of natural killer-cell activity⁵ and, as such cells are derived from bone marrow⁶, their activity is probably also restored in TIR mice. Depletion of T lymphocytes increases resistance to syngeneic tumours, and activated macrophages have been suggested as cells mediating such resistance⁷. The presence of lymphocytic infiltrates in the embryo-derived tumours obtained in nude and TIR mice supports the latter hypothesis. Because of the unique nature of these embryo-derived tumours we have been able to show that the T-cell status of the recipient mice affects the nature of the tumour (benign or malignant) in a situation where the incidence of tumours is unaffected.

Antigen-specific suppressive factor produced by a transplantable I-J bearing T-cell hybridoma

THE demonstration of a definite antigen-binding specificity possessed by suppressor T cells and suppressor factors¹⁻⁶ has provided an important strategy to determine the T-cell receptor for antigen. Although the gene coding for the determinant on the suppressor molecule has been unambiguously mapped in the I-J subregion of the mouse major histocompatibility complex (MHC)^{3,7}, the chemistry and the mode of action of the active molecule have been only poorly analysed—probably because of the difficulty in collecting sufficient materials from suppressor T cells for each studies. The establishment of T-cell hybridomas with specific suppressor function would provide an ideal tool to analyse the suppressor molecule and the mechanism of its action. We have been successful in obtaining a number of hybrid cell lines continuously secreting molecules having both antigen-specific suppressor function and I-J determinants. High frequency of fused cells with I-J determinants was reproducibly made by the combination of two procedures; the method to

Fig. 1 Growth of I-J^b positive hybridoma 9F181a in F₁ mice but not in mice with parental haplotypes. 2×10^6 9F181a cells in 0.1 ml were inoculated into C3H (H-2^b) (X), C57BL/6 (H-2^b) (Δ) or (C3H x C57BL/6)F₁ (H-2^b x b) mice (●). Tumour size was measured on the day indicated and expressed as the mean tumour area, being represented by the product of two perpendicular diameters. Each group consisted of four animals.

Table 1 Antigen-specific suppressive effect of secreted or extracted materials from the I-J^{b+} hybridoma 9F181a on the *in vitro* secondary anti-DNP IgG PFC responses

	Suppressor factor	Dose	Anti-DNP IgG PFC response to	
			DNP-EA	DNP-KLH

	Extract of 9F181a	3 × 10 ⁵ cells	1,697 ± 691	417 ± 107
Expt B	Not added	—	1,520 ± 274	1,492 ± 72
	Ascites of 9F181a-bearing mice	50 µl	1,521 ± 290	213 ± 73
		10 µl	1,307 ± 299	149 ± 88
		1 µl	1,379 ± 89	625 ± 368
		0.1 µl	1,648 ± 494	1,762 ± 137

4 × 10⁶ spleen cells from C57BL/6 mice primed with 100 µg of DNP-KLH or DNP-EA and 1 × 10⁹ pertussis vaccine 4 weeks before culture in Falcon 3008 plastic plate in 1 ml of RPMI-1640 (GIBCO) enriched with 10% fetal calf serum in the presence of 0.1 µg of antigen and 2 × 10⁻⁵ M 2-mercaptoethanol. The secreted or extracted materials from the hybridoma 9F181a were added to the culture at the start of cultivation. The culture was maintained in humidified atmosphere of 5% CO₂ in air at 37 °C. Anti-DNP IgM and IgG PFC were assayed on day 5 of culture by Cunningham and Szenberg as described previously². Expt A: 100 µl of the extract corresponding to 3 × 10⁵ BW5147 cells or hybridoma 9F181a cells was added to the appropriate group at the beginning of culture. For the preparation of the extract, cells were collected, washed three times with serum-free medium and resuspended with 0.01 M sodium phosphate-buffered saline pH 7.2 at a concentration of 1 × 10⁸ cells per ml. They were frozen in dry ice in acetone and thawed with warm water at 37 °C 10 times each. The cell-free extract was obtained by ultracentrifugation of the freezing and thawing materials at 20,000g for 1 h. Several other experiments gave similar results. Expt B: Various doses of ascites from (C57BL/6 × C3H)F₁ mice intraperitoneally implanted with 2 × 10⁷ hybridoma 9F181a cells 14 days previously were added at the beginning of the culture. Five other experiments gave similar results. Results are expressed as mean numbers of anti-DNP IgG PFC of four or five cultures ± s.d.

enrich antigen-specific Ig⁻ T cells from primed spleen cells by adsorption to and elution from antigen-coated Petri dishes, and the selection of I-J⁺ hybrids by sorting out with fluorescence activated cell sorter (FACS) after staining the fused cells with appropriate fluorescence reagents⁸. Here we report the derivation of an I-J bearing hybrid cell line, which is transplantable to H-2^{b/k} F₁ hybrid mice, secreting the antigen-specific suppressor molecule. Some physicochemical and immunochemical properties are also described.

The hybrids were made by fusion of AKR thymoma cell line BW5147, which lacks the enzyme hypoxanthine—guanine phosphoribosyl transferase (HGPRT⁻), with the suppressor T cell of C57BL/6 mice specific for keyhole limpet haemocyanin (KLH). The KLH-binding suppressor T cells were enriched by

allowing Ig⁻ spleen cells from KLH-primed mice to bind to KLH-coated Petri dishes⁹. Cells thus obtained constituted about 0.1–0.5% of the original spleen cells, but were enriched for the suppressor activity about 100-fold. The method for cell fusion used was as described elsewhere⁸. In brief, a mixture of 1 to 5 × 10⁶ enriched suppressor T cells and 1 to 50 × 10⁶ of BW5147 thymoma cells was suspended in Dulbecco's modified Eagle's medium (DMEM). The mixture was centrifuged at 400g and the pellet resuspended in 2 ml of polyethylene glycol (PEG; MW 2,000)—dimethyl sulphoxide (DMSO) solution (1 weight of PEG plus 1 volume of 15% DMSO-DMEM). Within 1 min, a further 2 ml of 50% (w/v) PEG solution without DMSO was poured into the test tube, and the reaction mixture gently stirred with a Pasteur pipette. The suspension was then gradually diluted with 16 ml of serum free DMEM and further diluted with 180 ml of DMEM containing 13% of fetal calf serum (FCS). They were then incubated at 37 °C in 5% CO₂ for 3–4 h. After incubation cells were washed four times with DMEM and cultured for 1 week in HAT medium (RPMI-1640 supplemented with 10% FCS and hypoxanthine, aminopterin, thymidine (HAT)) on Falcon plates (Falcon 3008), each well containing about 2 to 10 × 10⁴ cells in 1 ml. Cells grown in HAT medium were collected and stained with an anti-I-J^b antiserum (B10.A(5R) anti-B10.A(3R)) and fluorescein-conjugated rabbit anti-mouse Fab, both of which had been extensively preabsorbed with BW5147 cells to avoid nonspecific staining. The stained cells were then sorted by fluorescence activated cell sorter, FACS II (Becton-Dickinson), and fluorescence positive cells were cloned in multi-well microplates (Falcon 3040) by limiting dilution method or single cell manipulation.

Several hybridisation experiments have been carried out, and so far seven antigen-specific suppressor T-cell lines established. The detailed properties of these cell lines will be described elsewhere. The cell line 9F181a described here displayed certain characteristics not possessed by other functional T-cell hybridomas: this line was transplantable to H-2^{b/k} F₁ mice and secreted the antigen-specific suppressor molecule having I-J determinants, thus providing an opportunity to compare the suppressor molecules secreted and extracted from the suppressor T-cell hybridoma.

The transplantability of 9F181a was studied by inoculating 2 × 10⁶ cells in 0.1 ml intracutaneously into the shaved back of C57BL/6 (H-2^b), C3H (H-2^k) and (C57BL/6 × C3H)F₁ (H-2^{b/k}) mice respectively. The active growth of the tumour as a

20 µl of ascites or extracted materials from the 5 × 10⁵ hybridoma cells were absorbed by passing through the following immunoabsorbents: KLH (5 mg KLH per ml beads), *Ascaris suum* extract (5 mg protein per ml beads), anti-H-2^b (C3H.Q × HTH anti-C3H.B10; 1 ml γ-globulin fraction of antiserum per ml beads), anti-I-J^b (B10.A(5R) anti-B10.A(3R); 1 ml γ-globulin fraction of antiserum per ml beads), anti-I-J^k (B10.A(3R) anti-B10.A(5R); 1 ml γ-globulin fraction of antiserum per ml beads), polyvalent rabbit anti-mouse Igs (5 mg purified anti-mouse Ig antibodies per ml beads), and rabbit anti-mouse Fab (5 mg purified anti-mouse Fab antibodies per ml beads). The beads used were Sepharose 4B. The method for preparation of immunoabsorbents was as described previously³. The absorbed materials were added to the culture of spleen cells of C57BL/6 mice primed with DNP-KLH. The assay of anti-DNP IgG PFC is the same as in Table 1.

Table 3 Molecular weight of the suppressor factor in ascites of mice bearing 9F181a

Fraction added	Anti-DNP PFC per culture		% Suppression of IgG PFC
	IgM	IgG	
No factor	688 ± 58	2,544 ± 59	—
Fraction I	756 ± 58	2,956 ± 211	0
Fraction II	756 ± 365	2,590 ± 89	0
Fraction III	596 ± 89	2,865 ± 431	0
Fraction IV	779 ± 380	413 ± 325	84
Fraction V	668 ± 175	2,062 ± 325	19

The materials fractionated on Sephadex G-200 as indicated in Fig. 2 were concentrated by vacuum dialysis at 4 °C and tested for suppressive activity. The fractionated material at a dose corresponding to 30 µl of original ascites was added to the culture of spleen cells of C57BL/6 primed with DNP-KLH. Results are expressed as mean numbers of anti-DNP IgM and IgG PFC ± s.d. The degree of suppression was calculated as follows:

$$\% \text{ Suppression} = (1 - \text{experimental PFC/control PFC}) \times 100$$

solid form was observed in (C57BL/6 × C3H)_{F1} mice, but not in parental C3H or C57BL/6 mice (Fig. 1). If the cells were transplanted intraperitoneally into F₁ mice, a large quantity of ascites was produced. This ascites contained a strong antigen-specific suppressor activity (see below). The transplantability of 9F181a is partially explained by its surface phenotypic expressions: Even 13 months after hybridisation the cell line expressed H-2 antigens of both parental cells, H-2^b, and H-2^k, together with I-J^b determinants introduced from C57BL/6 suppressor T cells.

Previous studies have firmly established that the extract from sonicated splenic T cells of KLH-primed mice can specifically suppress the *in vivo* and *in vitro* secondary IgG antibody responses against DNP-KLH^{2,10}. The active molecule involved in this suppression was shown to carry determinants coded for by genes mapped in I-J subregion of MHC³. It was therefore of interest to establish whether the ascites as well as the extract obtained from this hybridoma contains a similar molecule having I-J determinants and antigen-specific suppressor activity. Various doses of ascites obtained from (C57BL/6 × C3H)_{F1} mice bearing 9F181a were added to the culture of 4 × 10⁶ DNP-KLH- or DNP-EA (hen's egg albumin: hapten coupled to irrelevant carrier)-primed C57BL/6 spleen cells which were concomitantly stimulated with the corresponding antigen (0.1 µg ml⁻¹) in the Mischell-Dutton culture system. A separate experiment was carried out to study the suppressive activity of the extract of 9F181a. The dose of extracted material corresponding to 3 × 10⁵ viable cells was added to the culture. The number of plaque forming cells producing anti-DNP IgG antibody was measured on day 5 by the method of Cunningham and Szenberg as described previously².

Fig. 2 Elution profile of ascites from mice bearing 9F181a after fractionation on Sephadex G-200. Two ml ascites was dialysed in 0.005 M borate buffered saline pH 8.0 for 16 h. The dialysed material was then fractionated on Sephadex G-200 column (2.5 × 90 cm × 2). Fractions (3 ml) were monitored by a spectrophotometer at 280 nm. Five fractions were separated as indicated, and were tested for suppressive activity (see Table 3). Arrows indicate the position of marker proteins (mouse IgM, mouse IgG, mouse albumin and hen's egg albumin: OVA) eluted at the identical condition. the MW of Fr. I is >200,000; Fr. II, 100,000–200,000; Fr. III, 70,000–98,000; Fr. IV 42,000–68,000; Fr. V, 30,000–40,000

The results in Table 1 show that addition of 1–50 µl of ascites to the cultured spleen cells suppressed anti-DNP IgG antibody response to DNP-KLH but not to DNP-EA. Even 10 µl of ascites showed a maximal suppressive effect, and 1 µl was enough to show a significant suppression. The extracted material from 9F181a also showed the same carrier specific suppressor activity, and the same dose of the extract from parental BW5147 had no effect on the response against both antigens. IgM antibody-forming cells to DNP-KLH which comprised 20 to 30% of total antibody secreting cells were not suppressed by both extracted and secreted materials (data not shown).

Immunochemical properties of the hybridoma-derived suppressor factors were studied by absorption with immunoadsorbents composed of specific antigen (KLH), irrelevant antigen (*Ascaris* extract), anti-H-2, anti-I-J, polyvalent anti-mouse IgG and anti-mouse Fab antibodies. As shown in Table 2, the suppressive activity of both ascites and extract was completely removed by KLH, anti-H-2^b and anti-I-J^b, but not by *Ascaris* extract, anti-I-J^k, polyvalent antimouse IgG and anti-mouse Fab. These results indicate that the suppressor molecules both secreted and extracted from 9F181a have an antigen-binding site and I-J coded determinants.

The molecular size of the hybridoma-derived suppressor molecule was investigated. Figure 2 shows the elution profile of

Table 4 Suppressive effect of extracted and secreted materials from 9F181a on the response of C57BL/6 and (C57BL/6 × C3H)_{F1} but not of C3H mice

Suppressor factor	Dose	Anti-DNP IgG PFC per culture		
		C57BL/6	(C57BL/6 × C3H) _{F1}	C3H
Not added	—	1,854 ± 288	3,424 ± 345	6,160 ± 725
Extract of BW5147	3 × 10 ⁵ cells	2,054 ± 245	3,194 ± 435	5,025 ± 1,109
Extract of 9F181a	3 × 10 ⁵ cells	134 ± 114	586 ± 122	5,382 ± 530
Ascites of 9F181a-bearing mice	20 µl	682 ± 272	1,008 ± 568	6,543 ± 1,264

Extract equivalent to 3 × 10⁵ BW5147 or hybridoma 9F181a cells and 20 µl of ascites was added to the culture of spleen cells of C57BL/6 (H-2^b), C3H(H-2^k) and (C57BL/6 × C3H)_{F1} (H-2^{b/k}) mice immunised with DNP-KLH and pertussis vaccine to test the requirement of H-2 histocompatibility for effective suppression. The numbers of anti-DNP IgG PFC after 5 days of culture with and without the factor were compared. Assay of anti-DNP IgG PFC as in Table 1.

ascites on Sephadex G-200. The fractionated materials as indicated in Fig. 2 were tested for their suppressive activity. This was present in fraction IV (Table 3). The MW of fraction IV was between 42,000 and 68,000—similar to that of previously reported suppressor factor from splenic T cells².

We have previously demonstrated that the suppressor T-cell factor from primed mice was able to suppress only the responses of H-2 histocompatible strains¹¹. Thus, we attempted to examine whether or not such a genetic restriction exists in the effect of the suppressor factor derived from the hybridoma 9F181a. As the cell line was made by fusion of BW5147 (H-2^b) and C57BL/6 (H-2^b) suppressor T cells, the secreted and extracted materials from 9F181a were tested for their activity to suppress the response mounted by spleen cells of parental haplotypes, H-2^k and H-2^b and of their F₁ hybrid (H-2^{b/k}). The results in Table 4 show that the responses of C57BL/6 and (C57BL/6 × C3H)F₁ were suppressed by both secreted and extracted materials, whereas that of C3H (H-2^k) was not. This result is consistent with the fact that I-J^b but not I-J^k is phenotypically expressed on 9F181a. The finding that the putatively homogeneous suppressor factor derived from the hybridoma had this strict H-2 restriction supports our previous postulate that the I-J bearing factor can interact with other types of lymphoid cells only if they share an identical I-J subregion¹¹.

A T-cell hybridoma with antigen-specific suppressor activity has recently been reported by Kontiainen *et al.*¹². The suppressive factor from their hybridoma was shown to suppress mainly the primary IgM antibody response, while the secondary IgG antibody response was less affected. The antigen-specific suppressor factor from our hybridoma preferentially suppressed secondary IgG response without measurable suppression of the IgM antibody response. The same was true for the hybridoma-derived factors reported by Taniguchi and Miller⁶ in the *in vivo* suppression of the secondary antibody response to other protein antigen, in which antigen-specific hybridoma derived factors could suppress only the IgG antibody response. Whether such a difference would be inherent to the structure of the factors is not yet known.

The establishment of T-cell hybridoma cell lines continuously producing homogeneous materials with antigen-specific activity would make possible a more exact analysis of the molecule and its mode of action. The transplantable hybridomas secreting a large quantity of the active molecules in ascites or in the culture supernatant would be of particular value in the study of the chemistry of the molecule.

We thank Drs S. Fujimoto, K. Hiramatsu, M. Yamada, I. Takei, M. Igarashi and Mr H. Takahashi for their help. This work was supported by a grant from the Ministry of Education, Culture and Science, Japan.

Interferon enhances the excitability of cultured neurones

INTERFERON has varied biological effects on cells^{1,2} and induces modifications of the cell surface both *in vitro*^{3–6} and *in vivo*⁷. The particular capacity of the neuronal membrane to generate propagated action potentials (well retained in culture⁸) makes neurones excellent material for the study of substances that affect the cell surface. We have therefore determined the effect of interferon on the electrical activity of nerve cells. Most of the experiments reported here were carried out on the cat cerebral and cerebellar cortex, because the electrical patterns of these structures have been well defined *in vitro*^{9,10}. Furthermore, as human leukocyte interferon exhibits a high degree of antiviral activity on cat cells¹⁰, we were able to study the effect of highly purified interferon preparations on the spontaneous and evoked electrical activity of these neurones. In other experiments, we studied the effect of rat interferon on rat neurones in culture. Our results, which show that human and rat interferon specifically enhance the excitability of cat and rat nerve cells, respectively, may have implications for the therapeutic use of interferon as well as for the understanding of some of the manifestations of viral diseases.

Explants of cerebral and cerebellar cortex from newborn kittens or rats were cultivated in Maximow assemblies at 35.5 °C in a drop of nutrient medium containing 40% fetal calf serum⁸. After 3 weeks, the culture was transferred into a moist chamber and fixed on the stage of an inverted phase contrast microscope.

Fig. 1 Effect of human leukocyte interferon on the spontaneous activity of a Purkinje cell (kitten cerebellar cortex, 43 d in culture). The upper (before interferon) and lower tracings (4 h after interferon) are recorded from the same cell for different sweep rates (a, b, c). Note that interferon increases the spike frequency and the duration of the burst (a). b and c (faster sweeps) show the tendency of the interferon-treated neurone to fire repeatedly (2–4 successive action potentials) compared with the single spike obtained from the same neurone before interferon. Horizontal bars, 100 ms; vertical bars, 1 mV, negativity downwards.

Under visual control, the two recording electrodes (glass micropipettes filled with 3 M KCl with a resistance of about 30 MΩ) were placed against the neuronal perikarya to record extracellularly the electrical activity of two neurones (or groups of neurones) for several hours. Focal electrical stimuli (15 V, 0.2–1 ms) were applied through a pair of electrodes (filled with isotonic saline, with the same resistance, 0.5–1 MΩ) which could be placed successively in various sites of the explant. The responses were amplified by a differential field effect transistor preamplifier (a.c. recording-time constant 250 ms), and stored on tape.

Table 1 Statistical analysis of the latency of 12 different cortical responses before and at least 1 h after addition of human leukocyte interferon

	After 25	13 $\pm$ 5.4*

Results were from three different kitten cerebral explants. Analysis by *t* test.* Highly significant, $P < 10^{-5}$.† $P < 0.0001$.

Crude human leukocyte interferon prepared as previously described¹¹ was purified over 3,000-fold and had a specific activity of 10^7 units per mg protein. It had a titre of 5.12×10^{-5} as assayed (using vesicular stomatitis virus) on both human diploid fibroblasts and cultures of kidney from the same kitten whose brain cortical cells were used in the experiment. A control human leukocyte preparation of approximately the same protein content (4 mg ml^{-1}) was prepared as previously described¹¹. Rat cell culture interferon prepared according to the techniques used in the production of mouse interferon¹² had a titre of 8×10^{-5} on rat fibroblasts and a specific activity of 8×10^5 units per mg protein. Because of the inherent complexity of the system it was only feasible to use a single interferon concentration for each species. We chose 10^4 human leukocyte interferon units and 8×10^3 rat cell culture interferon units.

When human leukocyte interferon was added to the culture medium of an explant from kitten cerebellar cortex there was an increase in the frequency of the spontaneous unit discharges and a tendency for individual neurones to fire repeatedly (Fig. 1). These changes were first observed after approximately 30 min and became more marked after several hours. In explants of kitten cerebral cortex the spike and slow wave pattern, which was usually observed at a frequency of about 1 per min, occurred every 30–40 s after the addition of interferon, and often showed a tendency to repeated firing. Rat interferon induced comparable effects on the neurones from newborn rat cerebellar and cerebral cortex. It is important to emphasise that although interferon induced quantitative modifications, it did not modify the basic spontaneous electrical pattern characteristic of these neurones⁸ (the cerebellar bursts¹³ and the cerebral spike and wave^{8,14}).

As interferon enhanced the spontaneous electrical activity of cat and rat neurones, we studied the effect of human interferon on the evoked electrical activity of cat neurones. In the experiments, the responses were plotted for different stimulating sites before and at various intervals after the addition of interferon. The general pattern of the evoked responses was similar to that characteristic of spontaneous activity and was reproducible for several hours. As in the experiments on spontaneous electrical

activity, an effect of interferon was first observed at approximately 30 min and persisted for the whole 4–5-h recording session.

The most important effect of interferon was a marked shortening of the latency between stimulation and the initial response (Fig. 2a, b). This decrease in latency was observed for all the stimulating sites at both recording electrodes, and the statistical analysis of these results is presented in Table 1. Interferon also lowered the threshold to stimulation. Thus, for a given intensity, a single shock (0.7–1.0 ms) evoked a single wave before interferon (Fig. 2c, upper tracings), whereas a similar but repetitive pattern was observed after the addition of interferon (Fig. 2c, lower tracings). Furthermore, the duration of the shock necessary to elicit a single response could be decreased from 0.7 ms to 0.3–0.2 ms after the addition of interferon. Lastly, when treated neurones were subjected to a repetitive stimulation, they were able to respond at a higher rate (6–8 potentials

Fig. 2 Patterns of evoked electrical activity in cultures of kitten motor cortex (a, c = 46 d) and hippocampus (b, d = 58 d) before (two upper tracings in each panel) and after (two lower tracings in each panel) treatment with 10^4 units of human leukocyte interferon. a and b illustrate the shortening of the latency after addition of interferon (see time in minutes in lower tracings) for the same stimulating site and for the same neurones. In c, a single shock of 0.7 ms evoked a single spike and wave from both neurones before interferon, and three successive spikes and waves 90 min after the addition of interferon. Note that the latency of the repetitive firing in the lower two tracings is considerably shorter than that of the single response shown in the two upper tracings. In d, two shocks at intervals of 250 ms evoked only two responses before interferon, whereas 2 h after the addition of interferon, three shocks at intervals of 175 ms still evoked three successive responses with a constant shortened latency. Note in all panels that the polarity and amplitude of the waves and the order of firing of both neurones remain unchanged after interferon. Horizontal bars, 20 ms; vertical bars 1.5 mV; negativity downwards. The length of the arrows indicating stimulation is directly proportional to the intensity of the current.

per s instead of 4–5 potentials per s) (Fig. 2d). It is interesting that interferon did not, however, increase the amplitude or modify the polarity of the electrical potentials.

We must stress that neither human nor rat interferon preparations was toxic for neurones in culture. The behaviour of interferon-treated cells did not change during the several hours of observation, and after staining (with Bodian silver impregnation) the neurofibrillar nets had the same normal morphological appearance as those in control cultures. Furthermore, when comparable amounts of human and rat interferon were added to fresh cat and rat explants, these cultures could be maintained for 1 month with interferon without any detectable damage.

The evidence that interferon was responsible for these effects may be summarised as follows. Only human leukocyte interferon, which exerts antiviral activity on cat cells, enhanced the spontaneous activity and evoked responses of cat cerebellar and cerebral cortex: a control leukocyte preparation and rat cell culture interferon did not exert these effects. Likewise, rat cell culture interferon, but not control preparations, enhanced the electrical activity of rat neurones.

An enhanced excitability of cerebral and cerebellar neurones in culture has also been observed using bicuculline¹⁵, picrotoxin¹⁵ and strychnine^{14,16}. Some of the effects of these substances (shortened latency, lowered threshold, tendency to repetitivity) are comparable to those we have described for interferon. Some striking differences do exist, however, between the effects of interferon on neurones and those reported for other pharmacological agents¹⁷. (1) Interferon treatment did not increase the amplitude or reverse the polarity of the cortical waves (as do most of the other excitatory substances). (2) The effect of interferon was seen after 30 min and lasted several hours. (Most other substances induce an immediate effect which lasts only a few minutes.)

Our data do not permit us to determine whether the enhanced excitability results from a direct effect on the neurone (modification of transmembrane ionic exchanges) or at the level of the synapse (facilitation of excitatory or blocking of inhibitory synapses). We believe this to be the first report of an effect of interferon on the function of nerve cells in culture. The nature of this effect is consistent with other known actions of interferon on cells, that is, enhancement of a particular cell function in the absence of cell toxicity¹². Although most of the effects of interferon require its incubation with cells for periods over 12 h, some early effects of interferon suggestive of modification of the cell surface have been observed within several hours; these include changes in thymidine transport¹⁸, release of labelled uridine¹⁹, and enhanced cytotoxicity of sensitised T lymphocytes²⁰ or natural killer cells²¹. However, the enhancement by interferon of the excitability of neurones within 30 min seems to be one of the earliest effects yet described.

Our observations may, however, be of more general interest. If the interferon-induced enhancement of neurone excitability in culture also occurs *in vivo*, our results may be relevant to some of the untoward manifestations of viral diseases.

We thank Mrs A. M. Legrand and Mrs M-T Bandu for technical assistance, and Drs Cantell and Mogensen for human leukocyte interferon and control preparations. This work was supported in part by grants from INSERM ATP 66-78-98 and the DRET (contract 78/210).

Stimulant effects of enkephalin microinjection into the dopaminergic A10 area

THE overt behaviour of various species is affected in different ways by opiate drugs. Mice and cats show behavioural stimulation following a systemic morphine injection whereas rats and dogs generally exhibit decreased behavioural activity^{1–4}, although in certain conditions, stimulant effects can also be seen in the latter species^{4,5}. Tatum *et al.* suggested that there are several distinct sites of action of opiate drugs in brain and that the relative dominance of one system over another determines whether the stimulant or depressant effects predominate⁴. Indeed, direct microinjections of morphine into the ventral tegmental area (VTA) have been shown to result in facilitation of self-stimulation behaviour whereas similar injections into the periaqueductal gray matter cause only an attenuation of this behaviour⁶. The discovery of endogenous ligands for opiate receptors in the brain⁷ has focused attention on the role of these peptides in various aspects of behaviour. Their analgesic properties following intraventricular and intracerebral injection are well documented⁸. Recently, it has been reported that infusion of α -endorphin into the substantia nigra induced stereotyped behaviour⁹, whereas local injections into the nucleus accumbens of the long-acting synthetic enkephalin analogue, [D-Ala²]-Met⁵-enkephalinamide (AME), produced an increase in locomotor activity¹⁰. We now report that infusion of AME (0.03–2.0 μ g) bilaterally into the dopaminergic (DA) A10 area of the VTA induces a short-latency behavioural stimulant effect reminiscent of effects produced by stimulation of the mesolimbic DA pathway¹¹. This effect is antagonised by pretreatment with the opiate receptor blocker naloxone.

Twenty-seven male Wistar rats, weighing 300–320 g, were anaesthetised with Nembutal (50 mg per kg), and two stainless-steel guide cannulae (23 gauge) were implanted stereotactically into an area 0.5 mm dorsal to the ventral tegmentum. Cannulae placements were confirmed histologically; the correct loci, quantified according to the coordinate system of König and Klippel, averaged $A = 2.1 \pm 0.3$, $L = 0.9 \pm 0.2$, and $DV = -2.6 \text{ mm} \pm 0.5$. Behavioural testing began 14 d after surgery.

Cannulae were sealed and kept patent by insertion of a 30-gauge inner stainless-steel stylet which protruded 0.5 mm beyond the outer guide. Microinjections were made by replacing each inner stylet with a 30-gauge needle attached to a micro-syringe by polyethylene tubing. A volume of 0.5 μ l was injected into each cannula over a 30-s period. The rats received injections of 2.0, 1.0, 0.12 or 0.03 μ g of AME or the vehicle (0.9% NaCl) on each side of the brain. Subjects were adapted to circular photocell cages for 2 h before injection and activity was measured for an additional 120 min after infusions into the

Fig. 1 Motility scores after microinjection of D-Ala²-Met⁵-enkephalinamide (AME, Calbiochem) or NaCl (0.9%) into the VTA. Ordinate: time in minutes; abscissa: number of times light beam interrupted per 10-min period (data presented are $\bar{x} \pm$ s.e.m.). a, Δ , $2 \times 0.12 \mu\text{g}$ AME ($n = 8$); $\bullet$, $2 \times 0.03 \mu\text{g}$ AME ($n = 8$). Total scores of both AME groups are significantly different from mean total scores of subjects injected with NaCl, O. ($P < 0.001$; 2-tailed t -tests.) b, $\blacksquare$, $2 \times 1 \mu\text{g}$ AME + NaCl (1 ml per kg, i.p.); $\square$, $2 \times 1 \mu\text{g}$ AME + naloxone (1.2 mg per kg in 1 ml per kg NaCl, i.p.). Mean total motility scores for the two groups are significantly different ($P < 0.02$, 1-tailed t -test). Arrow indicates injection. Whole-body locomotor activity was measured in circular photocell cages (60 cm diameter, BRS/LVE). In those animals receiving two drug injections, the injection sequence was balanced within the group and spaced at 48-h intervals. One day before the second injection $1 \mu\text{l}$ of 0.9% NaCl was infused through the cannulae to reduce possible misleading effects of residual drug deposits. Measurements were made during the light phase of the rat's diurnal cycle.

VTA. On one test, the subjects were pretreated with naloxone HCl (1.2 mg per kg intraperitoneally (i.p.)) immediately before bilateral infusions of $1 \mu\text{g}$ AME.

Figure 1 shows that bilateral injections of AME, in doses of $2 \times 1 \mu\text{g}$ ($n = 11$), $2 \times 0.12 \mu\text{g}$ ($n = 8$) or $2 \times 0.03 \mu\text{g}$ ($n = 8$), produced a clearcut increase in locomotor activity in all animals. This effect was evident in the first 10 min post-infusion and lasted up to 90 min. The mean total number of photocell counts for the $2 \times 1 \mu\text{g}$ dose was $2,656 \pm 367$ (s.e.m.) interruptions in 120 min. Seven additional animals were tested at the high dose of $2 \times 2 \mu\text{g}$ AME, which also led to a significant increase in the motility score ($2,781 \pm 300$ over 120 min). However, this score was not significantly different from that obtained with the $2 \times 1 \mu\text{g}$ dose and therefore the data were not included in Fig. 1. Significant increases in motility were observed in the groups receiving $0.12 \mu\text{g}$ and $0.03 \mu\text{g}$, with mean total counts of $1,930 \pm 163$ and $1,513 \pm 117$ per 120 min, respectively. Pretreatment with naloxone effectively antagonized the effects produced by $2 \times 1 \mu\text{g}$ AME (Fig. 1b). The activity score after naloxone was $1,616 \pm 234$ over 120 min, which was significantly less than the score obtained with a control dose of $2 \times 1 \mu\text{g}$ ($P < 0.02$ 1-tailed independent t test) but still above the score obtained after control infusions of NaCl ($\bar{x} = 828 \pm 68$ in 120 min $n = 16$).

The behavioural activation was defined more precisely by time sampling the behaviour of 11 rats according to a standard ethogram. The behavioural data indicated that the categories of

walking, rearing and sniffing were increased significantly only in the AME-treated group, at the expense of sleeping, sitting or lying quietly on the floor (Table 1). There was no indication of stereotyped behaviour such as repetitive head movements or prolonged sniffing on the same spot.

These results clearly indicate a behavioural stimulant effect after intracerebral infusions of AME into the VTA. No initial depressant effect was observed in any animal at any of the doses used. Although a significant stimulant effect was obtained with the lowest dose, there was evidence of a dose-response relationship, as the level of activity produced by this dose was significantly lower than that seen after the dose of $2 \times 1 \mu\text{g}$ ($P < 0.005$, 1-tailed t test).

Increased behavioural activity has been reported after microinjection of D-Ala into the nucleus accumbens¹⁰ and thalamus¹². However, the effects observed in the present study were obtained at much lower doses (0.03 – $2.0 \mu\text{g}$ compared with $10 \mu\text{g}$) and at significantly shorter latencies. This short-latency effect agrees with earlier observations of facilitation of self-stimulation behaviour following microinjection of morphine ($0.5 \mu\text{g}$) into the same area of the brain⁶. The antagonism of the behavioural stimulant effect of AME by naloxone is particularly important as it strongly suggests that the effect is mediated by opiate receptors.

Recent immunohistofluorescence data have identified enkephalin-positive perikarya in the interpeduncular nucleus, and enkephalin-containing nerve fibres in the VTA¹³. Thus, the present findings and the results of a previous localisation study with morphine⁶ suggest that the stimulant effects of AME are probably mediated by its action within the VTA or interpeduncular nucleus. The fact that infusions dorsal to this area were less effective (unpublished observations) is also consistent with this interpretation. It is important to recognise the difficulties in the precise localisation of intracerebral infusions. Thus, as the region of stimulation is inferred from the cannulae placements, the possible contribution of the adjacent substantia nigra cannot be ruled out. However, the behavioural data point to the involvement of the VTA in the effects reported here, as the increased locomotor activity and

Table 1 Effect on behaviour of $2 \times 2 \text{ g}$ D-Ala²-Met⁵-enkephalinamide (AME)

Behaviour	AME	Control	Statistic Z

Grooming	3.5 (0–10)	6 (0–23)	

For observations, the rats were placed in circular glass chambers (30 cm diameter) with bedding material distributed evenly over the floor, and given 1 h to adapt to this environment. The figures represent the number of occasions on which the specified behaviour was observed in the period 10–52 min after injection (median values and ranges are given for AME ($n = 6$) and control ($n = 5$) groups, respectively). Observations were made every 10 s during the first 2 min of each 10-min period (total: 60 samples per rat in 52-min test period). Statistical estimates were obtained with a Wilcoxon test (2-tailed). Walking + sniffing scored as walking; rearing + sniffing scored as rearing, sniffing + sitting or lying scored as sniffing.

* $P < 0.05$.

exploration elicited by AME are reminiscent of the intense exploratory activity seen after microinjections of dopamine into the nucleus accumbens¹¹.

The nucleus accumbens is one of the important projection areas of the DA cell bodies in the VTA¹⁴ and there is strong evidence for the involvement of this mesolimbic DA pathway in the stimulant effects of amphetamine and other related compounds¹⁵. Although the role of dopamine in the locomotor effects produced by AME injections into the nucleus accumbens is uncertain¹⁰, there is evidence that opiates may produce behavioural excitation by activating DA neurones¹². Recent electrophysiological data also support this contention¹⁶. Thus, it is tempting to speculate that the mesocorticolimbic DA system may mediate some of the locomotor stimulant effects of enkephalin in particular and opiates in general. The mesolimbic DA pathway has also been implicated in positive reinforcement¹⁷ and motivation¹⁸ and it remains to be determined whether this pathway might mediate the reinforcing properties of enkephalin¹⁹. If such a relationship were confirmed, it would have important implications for understanding the addictive properties of opiates.

Brain ACTH and endorphin reduced in rats with monosodium glutamate-induced arcuate nuclear lesions

IMMUNOASSAY and immunocytochemical techniques, in some instances with additional characterisation by bioassay and gel filtration, have demonstrated the presence of ACTH-like¹⁻¹⁰, β -lipotropin (LPH)-like^{6,9,11-13} and β -endorphin-like^{6,14,15} activity within the central nervous system. However, the source of these peptides in the central nervous system is uncertain³. Hypophysectomy is not associated with any change in hypothalamic content of ACTH^{1,5,10} or of β -endorphin-like material¹⁴, suggesting a non-pituitary, presumably central nervous system, origin. Immunoreactive perikarya containing

ACTH-like^{8-10,16,17}, β -LPH-like^{9,11,13,16,17} and β -endorphin-like¹⁵⁻¹⁷ material have thus far only been demonstrated in the arcuate nucleus and adjacent lateral areas of the mediobasal hypothalamus. We considered that if the arcuate nucleus were the source of ACTH-like activity within other areas of the central nervous system, its destruction would result in a decrease of such activity. Neonatal administration of sodium glutamate produces central nervous system lesions, restricted largely to neurones of the arcuate nucleus and to the retina¹⁸, while sparing fibres of passage¹⁹. We report here that, using neonatal sodium glutamate administration to produce such arcuate nucleus destruction in rats, the content of ACTH and β -endorphin-like material in the hypothalamus and other brain regions is markedly reduced in the absence of any change in whole pituitary, anterior lobe or plasma ACTH concentrations.

Timed pregnant Holzman rats were housed in air-conditioned quarters on a lighting schedule of 14 h light, 10 h darkness with *ad libitum* food and water. Female offspring received 2.0 mg per g monosodium glutamate (MSG) intraperitoneally on the 2nd and 4th days of life, and 4.0 mg per g on the 6th, 8th and 10th days of life²⁰. Animals were killed at 5 months of age. Another group of animals received five doses of 10% NaCl as an isotonic control.

Animals treated with MSG demonstrated the endocrinological, metabolic and behavioural abnormalities and the hypothalamic neurotoxicity (arcuate nucleus) characteristic of the MSG syndrome, in confirmation of our previous studies^{20,21}. Animals were decapitated, brains rapidly removed and mediobasal hypothalamus, medial preoptic area, amygdala and sections of cortex removed as previously described²². Five sections of a given area were homogenised in 2 ml 0.1 M HCl, a total of four pools of a given area being obtained from 20 animals. Anterior and neurointermediate pituitary lobes were separately removed, individually placed in 100 μ l HCl and frozen for subsequent assay. At that time 0.9 ml 0.1 M HCl was added to anterior and 0.4 ml to neurointermediate lobe and these were homogenised in a siliconised tube with a Teflon pestle. Trunk blood was obtained at the time of decapitation for immunoassay of plasma ACTH. Determination of immunoreactive ACTH¹ and endorphin²³ content of brain areas and of pituitary lobes was carried out as previously described; an aliquot of the homogenate was removed for measurement of protein concentration²⁴. Immunoassay of plasma ACTH was carried out by methods used in our laboratory²⁵. The ACTH antibody used exhibits approximately 8-30% cross-reactivity with the 31,000 molecular weight (31K) molecule, reacts on an almost equimolar basis with ACTH₁₋₂₄ and ACTH₁₋₃₉, and exhibits no cross-reactivity with α -MSH, β -MSH, ACTH₁₋₁₀, ACTH₂₅₋₃₉, β -LPH or α -, β -, or γ -endorphin. The β -endorphin antibody reacts with β -LPH, 31K ACTH and β -endorphin on a near-equimolar basis, but does not cross-react with γ -LPH, β -MSH or the enkephalins.

Glutamate-treated animals exhibited a highly significant reduction in immunoreactive concentrations of ACTH-like and β -endorphin-like material in the mediobasal hypothalamus, and also in the medial preoptic nucleus and amygdala. There were no significant changes in whole pituitary, anterior lobe or plasma ACTH content (Table 1). No significant difference in any of these parameters was noted among animals in different oestrous cycle stages.

These findings demonstrate: (1) that destruction of cell bodies of the arcuate nucleus is associated with a four- to fivefold decrease in detectable ACTH-like and endorphin-like immunoreactive material within the hypothalamus, and (2) that this occurs in the absence of any changes in whole pituitary, anterior lobe or plasma ACTH concentrations. These findings indicate that the arcuate nucleus is a major source of the cell bodies giving rise to fibre tracts containing ACTH and endorphin detected in hypothalamic and other sites. The lesser decreases in amygdalar concentrations might indicate that at least some of the immunoreactive material present in this area could arise locally, as suggested by Pacold *et al.*⁵, or that

surviving cell bodies (possibly in the mediobasal hypothalamic area adjacent to the arcuate nucleus) preferentially innervate the amygdala. Watson, Richard and Barchas¹⁰ have noted that when the β -LPH-positive cells (arcuate nucleus) were destroyed by hypothalamic lesions on one side of rat brain, there was also a reduction of staining for ACTH and β -LPH fibres.

Additional studies in enucleated animals, animals with stereotactically produced arcuate nuclear lesions, and deafferentation should show whether other areas affected by MSG administration are involved in the decrease in brain ACTH concentration seen in such treated animals. It is also unlikely that any of the endocrine effects associated with MSG administration²¹ (decreased growth, hypothyroidism and hypogonadism) are responsible, because, as noted, hypophysectomy is not associated with any change in brain ACTH concentration.

The data also demonstrate that brain concentrations of a pituitary-like peptide can vary independently of pituitary or plasma concentrations of that peptide. Similarly, marked alterations in pituitary and plasma ACTH concentrations following short or long term adrenalectomy are not associated with changes in median eminence or mediobasal hypothalamic ACTH concentrations²⁶. This, in addition to the data derived from hypophysectomised animals, suggests a non-pituitary source of these peptides, in keeping with our recent demonstration of synthesis of immunoreactive 31K ACTH/endorphin-like material²⁷ on incubation of dispersed bovine arcuate nucleus area with labelled precursor amino acid. (If ACTH/endorphin-like activity detected in arcuate nucleus perikarya represented a specific uptake and concentrating system of pituitary-derived material, with subsequent axonal transport and processing, this might explain the present findings, but not those of the labelled amino acid incubation studies.)

The MSG-lesioned animal might serve as a model to explore some of the behavioural effects of ACTH-related peptides, although the multiplicity of effects²¹ on other endocrine systems and neurotransmitters would limit the interpretations and specificity of such observations.

Nicotinamide is a brain constituent with benzodiazepine-like actions

BENZODIAZEPINES are a group of drugs with wide therapeutic application as anxiolytics, hypnotics, anticonvulsants and muscle relaxants. To exert their therapeutic and pharmacological effects, they apparently interact with a brain-specific benzodiazepine receptor characterised by a high-affinity binding site for this group of compounds^{1,2}. In analogy to the identification of morphine receptors in the brain and the subsequent isolation of opioid peptides, the discovery of the benzodiazepine receptor prompted the search for an endogenous brain constituent, which physiologically may display benzodiazepine-like actions³. We describe here the isolation and benzodiazepine-like actions of nicotinamide, a compound which might exert these actions in the brain physiologically.

From acetone or HClO₄ extracts of bovine or rat brain, three compounds were isolated by conventional column chromatography and identified by mass spectrometry, which showed some, although rather low, potency in inhibiting specific binding of ³H-diazepam to the benzodiazepine high-affinity binding site, tested *in vitro*¹: nicotinamide (IC₅₀ = 3.9 mM), hypoxanthine

($IC_{50} = 0.7 \text{ mM}$) and inosine ($IC_{50} = 0.9 \text{ mM}$). Of these, only nicotinamide showed the main neuropharmacological central effects characteristic of a benzodiazepine, described below, although, because only 0.3% enters the brain after injection into the internal carotid artery⁴, rather high doses of the compound are needed to elicit central effects after systemic application. However, nicotinamide showed the following effects on cat spinal cord activities, recorded as described previously^{5,6}, after local application by pressure ejection from a cannula ($0.5 \mu\text{l}$, $1 \times 10^{-4} \text{ M}$) placed close to the stimulating electrode in the dorsal horn. (1) Dorsal root reflexes (DRRs) induced by dorsal root stimulation were increased by 30–50%. (2) The excitability of primary afferents, as measured by antidromic potentials (APs) in dorsal rootlets, was unaffected, indicating a lack of direct interaction of nicotinamide with γ -aminobutyric acid (GABA) receptors. (3) Unconditioned monosynaptic ventral root reflexes (VRRs) were not affected. In contrast, presynaptic inhibition of monosynaptic VRRs, induced by conditioning and testing stimuli given to appropriate antagonistic muscle nerve afferents in the hind limb, was increased by 15–20% (Fig. 1). The GABA receptor blocker, (+)bicuculline (0.5 mg per kg , intravenously (i.v.)), inhibited these effects of nicotinamide.

Fig. 1 Enhancement of presynaptic inhibition in cat lumbo-sacral spinal cord by nicotinamide and its reversal by (+)bicuculline. Spinal cord activities of unanaesthetised spinal cats were recorded as described previously^{5,6}. Records are oscilloscope sweeps from one experiment, representative for all five cats tested, showing in four vertical columns from left to right: (1) Averaged dorsal root potentials (DRPs) including the superimposed dorsal root reflexes (eight consecutive responses) evoked in a dorsal rootlet (DR) L_7 by single supramaximal stimuli applied to a DR S_1 ; (2) antidromic potentials (APs) induced in a DR L_7 by constant submaximal volleys given by a semimicroelectrode to the dorsal horn S_1 ; (3) mono- and polysynaptic ventral root reflexes (VRRs) induced in a ventral rootlet S_1 by supramaximal stimuli applied to the nerve afferents of the gastrocnemius muscle; (4) same response as in (3) but now elicited in intervals of approximately 10, 20, 30, 50 and 100 ms following conditioning shocks to the nerve of the biceps femoris muscle. Saline and drugs were administered in the following sequence. Saline: recordings taken 3 min after pressure ejection of saline ($0.5 \mu\text{l}$) through a cannula (outer diameter $100 \mu\text{m}$) in close proximity to the stimulating electrode in the dorsal horn S_1 . Nicotinamide: recordings taken 3 min after the local application of nicotinamide ($0.5 \mu\text{l}$, $1 \times 10^{-4} \text{ M}$); dorsal root reflexes and presynaptic inhibition of conditioned monosynaptic VRRs were augmented. Bicuculline: (+)bicuculline (0.5 mg per kg , i.v.) injected when maximal effects of nicotinamide had been reached; reversed all effects of nicotinamide. Nicotinamide: the action of (+)bicuculline was overcome by the subsequent local injection of nicotinamide ($0.5 \mu\text{l}$, $1 \times 10^{-4} \text{ M}$). Interestingly, in this experiment the presynaptic inhibition by nicotinamide was more pronounced at the 100-ms interval than at shorter intervals, an effect observed only in two out of five cats.

However, the antagonistic action of (+)bicuculline was overcome by the subsequent administration of nicotinamide either locally ($1 \times 10^{-3} \text{ M}$, $0.5 \mu\text{l}$) (Fig. 1) or i.v. (300 mg per kg).

Electrophysiological effects, very similar in size and latency to those observed after local application of nicotinamide, were induced by local administration of the benzodiazepine⁷ Ro 11-7800 ($0.5 \mu\text{l}$, $1 \times 10^{-4} \text{ M}$) or an i.v. injection of diazepam (0.1 mg per kg). The action of both drugs was also reversed by (+)bicuculline. Nicotinic acid ($1 \times 10^{-3} \text{ M}$, $0.5 \mu\text{l}$ applied locally) had no effect on the cat spinal cord activities tested, indicating that the effect of nicotinamide was not due to a possible conversion to nicotinic acid. Inosine and hypoxanthine applied in the same way and at similar concentrations to nicotinamide were without effect on spinal cord activity.

In a conflict test, nicotinamide restored punishment-suppressed behaviour of rats, an action characteristic of clinically effective anti-anxiety agents. In a 1-h test session, in which level pressing for a food pellet reward was combined with an electric foot shock, pretreatment with nicotinamide increased moderately (500 mg per kg , intraperitoneally (i.p.)) and strongly ($1,000 \text{ mg per kg}$, i.p.) punished responding in 5 out of 10 animals.

The anticonvulsant action of nicotinamide was established in an assay highly sensitive for the anticonvulsant action of benzodiazepines. 3-Mercaptopropionic acid (MPA), an inhibitor of the GABA synthesising enzyme glutamic acid decarboxylase, was administered in a dose (50 mg per kg i.p.) precipitating seizures in 100% of the mice (20 animals) within 2–3 min. Nicotinamide (500 mg per kg , i.p.), injected 30 min before MPA, protected 25% of the animals from seizures. Hypoxanthine (500 and $1,000 \text{ mg per kg}$) was without protective effect and inosine was protective (25%) only at $1,000 \text{ mg per kg}$. Nicotinamide has also been shown to protect against audiogenic^{8,9} and isoniazid-induced¹⁰ seizures.

An anti-aggressive action of nicotinamide was demonstrated by the inhibition of aggressive rage reactions in unrestrained cats elicited by hypothalamic stimulation through chronically implanted electrodes¹¹. The current threshold needed to evoke a hissing response and an attack response was elevated by 15% ($P < 0.01$) after i.p. administration of nicotinamide (500 mg per kg , 4 cats) or diazepam (0.5 mg per kg , 4 cats) but not after inosine (500 mg per kg , 4 cats).

The muscle relaxant action of nicotinamide (300 mg per kg , i.p.) was observed in cats and rats. The sedative effect of the compound was apparent in cats (500 mg per kg , i.p.), confirming previous findings in rats^{12,13}, mice and gerbils^{13,14}.

Most remarkably, nicotinamide shows hypnotic action, previously analysed in mice and in man (250 mg per kg subcutaneously and 3 g d^{-1} , orally respectively). It manifests itself as a prolongation of total sleep time and an increase of rapid eye movement sleep^{15–17}, a response also seen after low doses of benzodiazepines^{18,19}. Finally, the finding that nicotinamide treatment increases the 5-hydroxytryptamine level in rat brain¹² is in line with the suggestion that the anxiety-reducing action of benzodiazepines is mediated by the reduction of 5-hydroxytryptamine turnover^{20,21}.

Thus, nicotinamide has properties in common with benzodiazepines (and barbiturates²²) in its action on spinal cord activity, its anticonflict, anticonvulsant, anti-aggressive, muscle relaxant and hypnotic action. It also seems to influence GABAergic mechanisms without binding to the GABA receptor itself, as shown by the electrophysiological findings and the lack of inhibition by nicotinamide of ^3H -GABA receptor binding tested according to Enna *et al.*²³.

If nicotinamide physiologically exerts benzodiazepine-like effects in the brain, its pharmacological potency should be high in view of its low concentration in the brain ($0.1 \mu\text{mol per g}$ rat whole brain)²⁴. This is supported by the electrophysiological experiments using *in situ* drug application, in which the potency of nicotinamide was found to be equivalent to that of a highly potent benzodiazepine. The low apparent affinity of nicotinamide to the benzodiazepine binding site *in vitro* may either

be due to shortcomings of the binding assay in reflecting the *in vivo* affinity of the endogenous ligand to that site, or the benzodiazepine receptor may be part of a receptor complex²⁵, which may contain more than one binding site through which benzodiazepine-like actions can be elicited in the brain. The hypothesis that nicotinamide may exert benzodiazepine-like actions in the brain physiologically, may shed new light on the mental disorders accompanying nicotinamide deficiency states.

We thank Dr W. Haefely for helpful criticism and Drs Vetter and Rinalder for gas chromatography/mass spectrometry measurements.

Immunocytochemical localisation of L-glutamic acid decarboxylase in the goldfish retina

A DIRECT way to examine whether certain neurones may use γ -aminobutyric acid (GABA) as a neurotransmitter is to determine by immunocytochemistry if L-glutamic acid decarboxylase (GAD), the enzyme responsible for GABA synthesis, is localised in these cells. We have been studying GABA-ergic pathways in the goldfish retina by autoradiographic and biochemical methods^{1–3}. It would therefore be of interest to localise the GAD-containing cells in this system immunocytochemically. However, although GAD has been purified from mouse brain⁴ and antibodies against the enzyme have been obtained, these antibodies do not cross-react with the GAD found in neural tissues of teleosts⁵. Thus, before immunocytochemical studies of GAD-containing neurones in the goldfish retina were possible, we had to purify GAD from teleost brain and obtain a specific antibody against this enzyme. Such an antibody has now been obtained⁶. We show here that in the goldfish retina, GAD is localised in specific interneurons: type H1 horizontal cells and probably type Ab pyriform amacrine cells. These cell types

have been shown to be both pre- and postsynaptic to red-sensitive cones and red-sensitive centre-depolarising bipolar cells, respectively^{3,7–9}.

Because we were able to obtain the channel catfish (*Ictalurus punctatus*) in large numbers, catfish brains were used for the purification of GAD⁶. The enzyme was extracted by homogenising 600 brains (about 300 g) in 3 l of water containing 0.1 mM pyridoxal phosphate, 1 mM EDTA, 1 mM 2-aminoethylisothionium bromide hydrobromide and 1 mM reduced glutathione, pH 7.2. About 70% of the GAD activity as measured by formation of both ¹⁴C-CO₂ and ¹⁴C-GABA (refs 4, 10) which was recovered in the supernatant after centrifugation of the homogenate at 100,000g for 45 min. The enzyme was purified to electrophoretic homogeneity by a combination of ammonium sulphate fractionation, gel filtration, calcium phosphate gel and preparative gel electrophoresis. Doses of 20 μ g of this enzyme were injected biweekly into two rabbits for 2 months. The ear veins were bled and serum was prepared by centrifugation at 2,000g for 20 min and used for immunocytochemical studies. Anti-catfish GAD immunoglobulins (IgG) from rabbit were prepared by passing the serum through a DEAE Sephacel ion-exchange column and eluting with 50 mM Tris buffer, pH 8.0. The IgG were used for immunodiffusion studies⁶.

GAD-containing neurones in the goldfish retina were localised immunocytochemically using the method of Dubois-Dalcq *et al.*^{11,12}. Eyes from light-adapted goldfish (*Carassius auratus*) were enucleated and isolated eyecups were fixed with 4% paraformaldehyde in isotonic phosphate-buffered saline (PBS; 100 mM NaCl and 25 mM sodium phosphate, pH 7.2) for 1 h at room temperature and overnight at 4°C. Each eyecup was then washed with PBS, cut radially into strips several mm wide, embedded in agar and sectioned at 50 μ m with a vibratome. Sections were incubated at room temperature for 2 h with a 1:250 dilution of rabbit-anti-catfish GAD serum (1:50 to 1:1,000 dilutions of the antiserum give similar staining patterns) or non-immunised serum (control), then washed with PBS and

Fig. 1 Ouchterlony double diffusion test with crude GAD from goldfish brain, goldfish retina and catfish brain. Each well contained 15 μ l of solution. Anti-catfish GAD IgG (70 μ g) was in the central well. Wells a to f were homogenates from goldfish brain (a, b), goldfish retina (c, d) and catfish brain (e, f), respectively. The diffusion plate was kept at 4°C for 48 h, washed with PBS at room temperature for 48 h, stained with 1% Coomassie blue for 20 min and destained with 7% acetic acid for 2 h. The spurs between f and a, and d and e suggest that catfish and goldfish GAD are not identical enzymes. However, the formation of a single, sharp precipitin band in b and c indicates that the antibody against catfish GAD cross-reacts strongly and specifically with goldfish GAD.

Fig. 2 *a, b*, Immunocytochemical localisation of GAD in 50-μm sections of goldfish retina. Focusing on the outer retina (*a*), HRP-staining is seen over the somata of some cone horizontal cells (*h*). Note that the nuclei of these cells are not stained and therefore probably do not contain GAD. Scale bar 20 μm. Focusing on the inner retina (*b*), HRP-staining is seen over some amacrine cells (*a*, the nucleus is not stained) and in sublamina b of the inner plexiform layer, indicating that GABAergic terminals are probably concentrated in this sublamina (*b*). Note dense HRP-staining around the axon terminal (*at*) of a type b bipolar cell^{3,8,9}. *c*, Control experiment, where a section treated with non-immunised serum shows very little HRP staining. The dark structures between photoreceptors are melanin granules in pigment epithelial cells. *d*, HRP-staining of GAD in a 5-μm section shows that some somata and axons of cone horizontal cells, probably H1 cells are stained. Sublamina b of the inner plexiform layer is also stained, especially around the axon terminal of some type b bipolar cells. *e*, Autoradiographic section of a goldfish retina incubated with 10^{-6} M ^{3} H-GABA. As shown earlier^{1,3}, high-affinity GABA uptake is localised in the somata and axons of H1 horizontal cells, and in some Ab pyriform amacrine cells which make synaptic connections in sublamina b of the inner plexiform layer. *f*, Schematic diagram of probable GABA-ergic neurons (H1 horizontal cells and some Ab amacrine cells) and their functional connections in the goldfish retina as revealed by our immunocytochemical and autoradiographic studies. rc: red-sensitive cones; sh₁ and ah₁: soma and axon of a H1 cell; rb: red-sensitive centre-depolarising bipolar cell (type b); a: pyriform amacrine cell which makes contact with rb; g: retinal ganglion cell.

treated for 2 h with a conjugate of horseradish peroxidase (HRP) and protein A¹¹. After washing, the sections were incubated with diaminobenzidine and hydrogen peroxide¹³. The sections were then fixed in 3% glutaraldehyde in 100 mM phosphate buffer (pH 7.4) for 1 h, dehydrated in ethanol, rinsed with xylene, and immersed in cedarwood oil. The HRP reaction products in these sections were visualised by Nomarski differential interference microscopy. The sections were then embedded in a thin layer of epoxy and sectioned tangentially at 2–5 μm for light microscopy.

Several lines of evidence indicate that the GAD purified from catfish brain and used as the antigen is homogeneous, and that

the antibody against catfish GAD is monospecific⁶. First, in several different polyacrylamide gel electrophoresis systems, the purified enzyme migrated as a single band which contained all the GAD activity. Second, immunoprecipitation studies showed that the antibody inhibited 67% of the GAD activity from catfish brain. Third, the Ouchterlony double immunodiffusion test showed only one sharp precipitin band between the antibody and catfish brain extract (Fig. 1). Finally, this precipitin band contained 86% of the GAD activity on the immunodiffusion gel⁶.

The formation of only one sharp precipitin band between the anti-GAD serum and goldfish brain and retina shows that

goldfish GAD cross-reacts strongly with this antibody. Using the antibody, our immunocytochemical study shows that GAD is localised in some horizontal cells, a few amacrine cells and sublamina b of the inner plexiform layer (Fig. 2). In the goldfish retina, different types of horizontal cells can be classified physiologically and morphologically according to their functional contacts with photoreceptors⁷. Thus, rod horizontal cells receive input exclusively from rods, and cone horizontal cells can be subdivided into H1, H2 and H3 cells, which receive input predominantly from red, green and blue-sensitive cones, respectively. The positions of the HRP-labelled horizontal cells in the inner nuclear layer indicate that these are the perikarya of H1 horizontal cells. To enhance HRP staining in cell bodies and axons of GAD-containing cells, 50- μ m sections were incubated with 0.1% Triton X-100 and the anti-GAD serum (a 1:4,000 dilution was used for most Triton X-100 treated tissue) overnight before the normal immunocytochemical procedure¹⁴. With this treatment, both the perikarya and axons of some horizontal cells are heavily stained (Fig. 2). Again, the positions of the HRP-stained cell bodies indicate that these are H1 horizontal cells. It follows that the HRP-stained axons are most probably axons of H1 cells. H2, H3 and rod horizontal cells, photoreceptors, bipolar cells and Müller (glial) cells do not show detectable HRP staining for this enzyme.

The identities of the HRP-stained amacrine cells cannot be determined without serial reconstruction and electron microscopic studies. The presence of GAD in sublamina b of the inner plexiform layer, especially around the axon terminals of some centre-depolarising bipolar cells (type b)^{8,9}, suggests that GAD-containing amacrine cells make synaptic contacts with these bipolar cells. This result and those of autoradiographic studies of ³H-GABA uptake in the inner plexiform layer, indicate that at least some GABA-ergic amacrine cells are Ab pyriform cells which make contact with red-sensitive centre-depolarising bipolar cells in the goldfish retina^{3,8,9}.

Comparison between the immunocytochemical studies of GAD-containing neurones and autoradiographic studies of GABA uptake reveals a marked similarity in the labelling patterns (Figs. 2, 3). Our findings therefore demonstrate that in goldfish retina, the neurones which possess a high-affinity system for GABA uptake also contain significant levels of GAD. In addition, this study confirms earlier biochemical results showing that at least some isolated axons of cone horizontal cells in the goldfish retina synthesise GABA and contain high specific activities of GAD². These findings, and

those of autoradiographic^{1,2} and electrophysiological¹⁵ studies of the GABA system in the teleost retina, point to GABA as being the transmitter used by H1 horizontal cells of the goldfish retina. The absence of GABA uptake and GAD in all other horizontal cell types (H2, H3 and rod) indicates that they are not GABA-ergic. This raises the possibility that horizontal cells which are in contact with different types of photoreceptors may use different neurotransmitters.

Fig. 3 A 3- μ m section of a goldfish retina treated with 0.1% Triton X-100 and anti-GAD serum (1:4,000 dilution) overnight and processed for immunocytochemistry. Because this treatment enhanced the penetration of the antiserum and conjugate into the tissue, HRP staining is much more intense than that shown in Fig. 2. In particular, both the somata and axons of the H1 horizontal cells are clearly stained. Scale bar 20 μ m.

Identification of β -adrenergic-sensitive adenylate cyclase in intracranial blood vessels

THE regulation of cerebral blood flow and vascular permeability is important in such clinical conditions as stroke, arterial spasm, vascular headache (for example, migraine) and metabolic effects of seizures. Unfortunately, relatively little is known about the nervous control of cerebral circulation, particularly with regard to the nature of the hormone and neurotransmitter receptors present in cerebral vessels. An influence of the adrenergic nervous system has been suggested by histological studies showing that the blood vessels and branches of the circle of Willis receive innervation from the sympathetic chain¹, and that the smaller, penetrating cerebral vessels (called microvessels) are surrounded by noradrenaline-containing fibres which seem to arise from brainstem noradrenergic nuclei^{2,3}. Although attempts to demonstrate β -adrenergic receptors in cerebral vascular tissue by cytochemical methods have been unsuccessful⁴, indirect evidence for the presence of such receptors is

suggested by reports that adrenergic stimulation can alter cerebral blood flow and vascular permeability^{3,5}, and that catecholamine agonists (such as isoprenaline and adrenaline) can dilate whole-artery preparations of cerebral vessels⁶. We now report the presence of a β -adrenergic-stimulated adenylate cyclase in both superficial and deep cerebral blood vessels. In addition to supplying direct biochemical evidence for the existence of β -adrenergic receptors in the cerebral vasculature, identification of this enzyme should facilitate the evaluation of the actions of pharmacological agents on cerebral blood flow and vascular permeability.

Previous studies have demonstrated that the receptors for several neurotransmitters and circulating hormones are intimately associated with the membrane-bound enzyme, adenylate cyclase, and that activation of this enzyme, resulting in the intracellular formation of cyclic AMP, mediates the effects of the hormone or neurotransmitter⁷. To demonstrate the possible existence of a β -adrenergic-stimulated adenylate cyclase in cerebral vascular tissue, the effects of various catecholamines on the enzymatic synthesis of cyclic AMP from ATP were studied. Broken cell preparations of three types of mammalian blood vessels were used: superficial arteries and proximal pial branches of the circle of Willis; penetrating (intraparenchymal) microvessels; and extracranial carotid arteries. The microvessels were prepared by a modification of published techniques^{8,9}, involving mechanical fragmentation, discontinuous sucrose gradient centrifugation, and sieve filtration (see Fig. 1 legend). Feline blood vessels were used for most experiments, as previous studies have demonstrated a rich

noradrenergic innervation in the cerebral vasculature of this species^{10,11}, and physiological studies have documented β -adrenergic-mediated vasomotor responses of cat pial arteries⁶. In preliminary experiments, dog and calf pial vessels also demonstrated β -adrenergic-stimulated adenylate cyclase activity, but the degree of stimulation was less than that in the cat.

Figure 1a shows the effects of (-)isoprenaline (Iso), a β -adrenergic agonist, on adenylate cyclase activity in an homogenate of cat pial vessels. In the experiment shown, maximal stimulation by Iso was 160% of control activity and, in other experiments, varied between 150% and 180% of control. Concentrations of Iso as low as 10^{-7} M caused significant stimulation, and half-maximal activity occurred at a concentration (K_d) which varied between 4 and 11×10^{-7} M. (-)Noradrenaline (NA), a mixed β - and α -adrenergic agonist, was less effective than Iso in stimulating enzyme activity (150% of control in pial vessels), whereas (-)phenylephrine, an α -adrenergic agonist, caused only minimal stimulation at comparable concentrations.

Activation of adenylate cyclase activity by Iso and NA was more pronounced in preparations of cat intraparenchymal microvessels (Fig. 1b), varying between 170 and 225% of control activity for Iso and 165 and 220% for NA, at maximum. In the experiment shown, the K_d for Iso was 3×10^{-7} M. In contrast, none of the catecholamines had any effect on the adenylate cyclase activity present in homogenates of cat common and proximal external carotid artery (Fig. 2).

Results similar to those above were obtained with both pial vessels and microvessels from cats which had been perfused systemically to remove intravascular blood. The finding that whole blood, itself, showed little Iso-stimulated enzyme activity, made it unlikely that blood elements contributed to our results. In contrast to the effects observed in vessels, stimulation of whole brain adenylate cyclase by a maximally effective concentration (100 μ M) of Iso was only 128% of control activity (Fig. 2). On the other hand, 100 μ M dopamine (DA) activated the enzyme activity of brain (150% of control) more than that of either pial vessels (130%) or microvessels (124%). Also, further evidence differentiating brain from vessel adenylate cyclase was obtained from the observed effects of GTP, which (at 100 μ M) activated basal enzyme activity of cat brain homogenates by 600% but those of pial vessels and microvessels by only 200%.

Fig. 1 Effects of (-)isoprenaline (●), (-)noradrenaline (▲) and (-)phenylephrine (■) on adenylate cyclase activity in broken cell preparations of cat cerebral vasculature. *a*, Pial arteries, control activity = 13.8 ± 1.6 pmol per mg protein per min. *b*, Intraparenchymal microvessels, control = 11.5 ± 0.7 pmol per mg protein per min. Values shown are the means ($\pm$ deviation) of replicate samples, each assayed for cyclic AMP in triplicate. For these studies, male cats were anaesthetized with ether and perfused transcardially with 500 ml of phosphate-buffered saline (PBS). Superficial arteries (distal vertebral, basilar, intracranial carotid, proximal portions of anterior, middle and posterior cerebral) were dissected and cleaned of adhering pia, rinsed in PBS, and homogenized (20 mg ml^{-1}) in cold 6 mM Tris-maleate buffer, pH 7.4. To isolate microvessels, the brain was stripped of remaining pia, coarsely minced, and gently homogenized by hand (six vertical strokes, no rotation) in a Teflon-glass homogeniser (0.2 mm clearance) in 60 ml cold 25 mM Tris-maleate buffer, pH 7.4, containing 140 mM NaCl and 0.5% bovine serum albumin (buffer A). After centrifugation at 1,500 g for 15 min, the precipitate was resuspended in 2 vols 0.25 M sucrose and centrifuged (25,000 r.p.m. for 50 min) on a discontinuous 1.0/1.8/2.25 M sucrose gradient. The resulting 1.0/1.8 M and 1.8/2.25 M fractions were diluted in buffer A, centrifuged at 4,000 g, the pellet resuspended in 0.25 M sucrose, and centrifuged (25,000 r.p.m. for 40 min) on a 1.0/1.35/1.5/1.7/2.25 M sucrose gradient. The microvessel fraction (combined 1.5/1.7 M and 1.7/2.25 M interfaces) was washed and collected against a 100- μ m Nitex screen and homogenized (15 mg ml^{-1}) in 6 mM Tris-maleate, pH 7.4. Vessel purity was monitored through the use of light microscopy and enzyme markers¹⁵. Cyclic AMP formation was measured in tubes containing (in 0.3 ml) 80 mM Tris-maleate, pH 7.4, 10 mM theophylline, 6 mM MgSO_4 , 0.1 mM GTP, 1.5 mM ATP, and tissue homogenate (1.0–1.5 mg wet weight), plus test substances as indicated. The reaction (4 min at 30 °C) was initiated by addition of ATP, stopped by heating to 90 °C for 2 min, and then centrifuged to remove insoluble matter. Cyclic AMP was measured as in ref. 16. In these conditions, enzyme activity was linear with time and enzyme concentration, and phosphodiesterase activity was nearly completely inhibited. All experiments were replicated 2–5 times. The results shown in Figs 1 and 2 and Table 1 represent typical experiments.

Fig. 2 Comparative effects of 100 μ M (-)-isoprenaline ($\square$), (-)-noradrenaline ($\blacksquare$) and dopamine ($\square$) on adenylate cyclase activity in homogenates of whole cat brain (control activity = 37 ± 1 pmol per mg protein per min) and three preparations of cat vasculature: intraparenchymal microvessels (control = 13.8 ± 0.6 pmol per mg protein per min); superficial pial vessels (control = 12.3 ± 0.9 pmol per mg protein per min); and common and external carotid artery (control = 1.3 ± 0.2 pmol per mg protein per min). The values shown here and in Table 1 are the means ($\pm$ deviation) of replicate samples, each assayed for cyclic AMP content in duplicate.

and 120%, respectively. In contrast to effects on basal activity, Iso stimulation, itself, had an absolute requirement for the presence of exogenous GTP. Other experiments indicated that, unlike adenylate cyclases activated by DA, histamine and serotonin, present in other tissues⁷, Iso-stimulated adenylate cyclase activity in cerebral vessel homogenates was unaffected by calcium chelation with EGTA (calcium did affect basal activity).

The preferential activation of a β -adrenergic receptor by Iso in cerebral vessel homogenates was supported by other experiments using receptor antagonists. Table 1 shows that Iso-stimulated adenylate cyclase activity in a microvessel homogenate was almost completely blocked by the β -adrenergic antagonist, propranolol, but was less affected by the α -adrenergic

antagonist, phentolamine, or the potent DA antagonist, fluphenazine. Similar results were seen in homogenates of pial vessels. Table 1 also demonstrates the non-additive effects of Iso, NA and DA on microvessel adenylate cyclase, results supporting the activation of a single class of receptors.

Taken together, these data demonstrate the presence of a β -adrenergic-sensitive adenylate cyclase in cat intraparenchymal and extraparenchymal cerebral blood vessels. Because of the known association of adenylate cyclase with β -adrenergic receptors in other tissues^{12,13}, identification of this enzyme strongly supports the existence of a β -adrenergic receptor in the mammalian cerebral vasculature. It will be of interest to determine the cellular localisation of β -adrenergic-sensitive adenylate cyclase within the blood vessel wall; a presence in endothelial cells might suggest an involvement in vascular permeability, or a media localisation, an involvement in vasomotor responses. In addition, further characterisation of the cerebral vasculature β -adrenergic receptor, itself, should prove helpful in evaluating and comparing the actions of adrenergic agents (such as β_1 and β_2 selective types) in both intraparenchymal and extraparenchymal cerebral vessels.

Table 1 Effects of various compounds on adenylate cyclase activity

Agent	Cyclic AMP increase (pmol per mg protein per min)
a Antagonists	
Iso (100 μ M)	11.5 $\pm$ 0.9
Iso (100 μ M) + Prop (10 μ M)	4.6 $\pm$ 1.0
Iso (100 μ M) + Phent (10 μ M)	11.1 $\pm$ 0.6
Iso (100 μ M) + Flu (10 μ M)	11.8 $\pm$ 0.4
Iso (100 μ M) + Prop (50 μ M)	1.0 $\pm$ 0.6
Iso (100 μ M) + Phent (50 μ M)	7.3 $\pm$ 0.3
Iso (100 μ M) + Flu (50 μ M)	7.4 $\pm$ 0.4
b Additivity	
Iso (1 mM)	13.1 $\pm$ 0.1
NA (1 mM)	12.0 $\pm$ 0.5
DA (1 mM)	10.4 $\pm$ 0.4
Iso (1 mM) + NA (1 mM)	12.9 $\pm$ 0.4
Iso (1 mM) + DA (1 mM)	12.9 $\pm$ 0.9

a, Effects of the β -adrenergic antagonist, propranolol (Prop), α -adrenergic antagonist, phentolamine (Phent), and dopamine antagonist, fluphenazine (Flu), on activation of adenylate cyclase activity by (-)-isoprenaline (Iso) in an homogenate of cat cerebral microvessels. **b**, Effects of maximally effective concentrations of Iso, (-)-noradrenaline (NA), and dopamine (DA), alone and in combination, on adenylate cyclase activity in another preparation of microvessels. Qualitatively similar results were obtained in additivity experiments using 10-fold lower amine concentrations. The values shown in **a** are the increases due to Iso over enzyme activity in the presence of antagonist alone. In the absence of added agents, control activity was 13.1 ± 1.1 pmol per mg protein per min in **a** and 17.7 ± 1.1 pmol per mg protein per min in **b**.

Distribution of muscarinic acetylcholine receptors in amphibian cardiac muscle

THE skeletal muscle-nerve junction and many interneuronal synapses are highly specialised and morphologically characterised by a direct apposition of pre- and postsynaptic elements separated by a cleft of no more than 50 nm, localised thickenings of the apposed membranes and an aggregation of small vesicles in the presynaptic process. At several such 'focal' synapses, neurotransmitter receptor molecules are restricted to patches of postsynaptic membrane corresponding to synaptic sites¹⁻³. For example, at the motor endplate of skeletal muscle, acetylcholine receptor packing density in the subsynaptic membrane is about 10^3 times higher than in the extrasynaptic membrane several μ m away⁴⁻⁶. Many neuroeffector junctions such as those in autonomically innervated tissues, however, are much less specialised and lack synaptic membrane apposition and thickenings^{7,8}. In the heart for example, the terminal postganglionic autonomic axons consist of long chains of vesicle-packed varicosities and

Fig. 1 Two cardiac muscle fibres in a *Xenopus* interatrial septum stained with zinc iodide and osmium. A fresh interatrial septum pinned to a Sylgard-coated cover slip was incubated overnight in ice-cold zinc iodide and osmium. Zinc iodide was made by mixing 2 g Zn dust and 1 g I_2 in 40 ml H_2O . 2 ml of the filtered zinc iodide, 0.5 ml of 2% OsO_4 , and 6 ml of 0.2 M sodium acetate buffer pH 3.9 were mixed to make the zinc iodide and osmium stain (M. Letinsky, personal communication). Scale bar, 20 μm .

form a widely ramifying plexus over the muscle⁹. The varicosities sometimes lie in close apposition to the muscle but may often be several μm away from the nearest target. Even when pre- and postsynaptic membranes are closely apposed, morphological specialisation of the membranes is not normally seen^{7,10-12}. I was interested to determine whether receptor molecules for acetylcholine (ACh) in heart muscle are localised to the relatively infrequent sites of close apposition between nerve and muscle or are more generally distributed. This report demonstrates that muscarinic ACh receptors are uniformly distributed in cardiac muscle fibres in amphibian heart.

Distribution of muscarinic ACh receptors was determined by autoradiography of cardiac muscle labelled with ^3H -quinuclidinyl benzylate (QNB). QNB (Roche) has been shown to bind strongly and with high specificity to muscarinic ACh receptors in mammalian cardiac muscle¹³ and other tissues¹⁴. Similar binding properties of QNB in amphibian heart have recently been found (H.C.H., in preparation). Before autoradiography, conditions for labelling muscarinic ACh receptors with ^3H -QNB were determined by scintillation counting. Pieces of *Xenopus laevis* atrium were incubated with various concentrations of ^3H -QNB for 1.5 h, washed in ice-cold Ringer solution for 10 h and counted. Specific binding, defined as the difference between binding in the presence and absence of 100 nM unlabelled QNB or 1 μM atropine¹³, was saturable with a single apparent K_D of 1.0 nM. Nonspecific binding in the presence of 100 nM unlabelled QNB was nonsaturable. At a saturating concentration of 2.5 nM ^3H -QNB, atrial tissue contains 369 fM specific QNB binding sites per mg Lowry protein and 85 fM mg^{-1} nonspecific binding. Thus, 82% of the total binding is specific in these conditions. Autoradiographic experiments, however, show that most of the nonspecific binding occurs at the ends of muscle fibres which have been damaged or cut. Dissociation of bound ^3H -QNB from receptor was determined using atrial homogenates as described by Fields *et al.*¹³. At 4°C the $t/2$ of dissociation ranged from 20 h to >48 h in five experiments. As tissues processed for autoradiography were washed at 4°C for less than 10 h not more than 20% of the bound ^3H -QNB dissociated during the washing.

Muscarinic ACh receptor distribution was determined by autoradiography of whole mounts of *Xenopus* interatrial septum and sinus venosus. These tissues were chosen because they are very thin sheets, usually not more than 20 μm thick and are thus natural tissue sections¹⁵.

Figure 1 is a micrograph of a portion of interatrial septum stained with zinc iodide and osmium¹⁶ (ZIO) which stains axonal

varicosities black. The diffuse nature of the pattern of innervation is evident. ZIO-stained varicosities measure $1.05 \pm 0.45 \mu m$ in the short dimension by $1.44 \pm 0.48 \mu m$ in the long dimension (mean $\pm$ s.d., $n = 70$). Thus, an average varicosity has a cross-sectional area of $4.8 \mu m^2$. As the density of varicosities on the muscle fibres is $\sim 0.016 \mu m^{-2}$ in the interatrial septum

Fig. 2 *a*, Autoradiograph of a fibre in *Xenopus* interatrial septum labelled with ^3H -QNB. The septum was incubated in 2.5 nM ^3H -QNB (NEN, 29.4 Ci $mmol^{-1}$) in frog Ringer solution for 1.5 h, washed with numerous changes of ice-cold Ringer for 2 h, fixed for 30 min in 1% glutaraldehyde buffered with sodium phosphate, pH 7, and washed in Ringer for an additional 7 h. The thinnest portions of the preparation were cut out, placed on a microscope slide with a drop of ice-cold 2% bovine serum albumin in distilled water and rapidly dried in a stream of air at 4°C. A thin layer of carbon was evaporated onto the slide and the slide coated with emulsion by a method similar to that described by Lane *et al.*¹⁷. *b*, Same field as *a* stained with toluidine blue to illustrate cellular composition of the septum. The N-shaped strands are septal myocardial fibres which are embedded in a network of connective tissue cells whose nuclei stain darkly. *c*, Autoradiograph of a preparation incubated in 2.5 nM ^3H -QNB and 100 nM unlabelled QNB to demonstrate nonspecific binding. *d*, Same field as in *c* stained with toluidine blue. Autoradiographs were exposed for 14 d. These fields are representative of seven preparations. Scale bar, 50 μm .

(manuscript in preparation), it is estimated that at most 8% of the muscle surface is synaptic; since some of the varicosities are located several μm from the muscle, focal synaptic area is probably less than 8%.

Figure 2*a* is an autoradiograph of a muscle fibre labelled with ^3H -QNB in the interatrial septum. Silver grains are distributed over the entire surface of the muscle fibre. Most fibres in a given preparation exhibit a similar grain density, although occasional fibres are seen which have few grains. Silver grains are seen at much lower density over non-muscle tissue including connective tissue, endothelial cells and neurones. As the high density of silver grains is localised to the muscle fibres, little or no diffusion

Fig. 3 Frequency distribution of silver grains of ^3H -QNB-labelled fibre. The number of $25\text{-}\mu\text{m}^2$ areas containing different numbers of silver grains are shown as a histogram (open bars). Data from cell shown in Fig. 2a. Average grain density is 1.72 grains per $25\text{-}\mu\text{m}^2$. This value was used for calculating the expected Poisson distribution (stippled bars). The calculated χ^2 value was 1.02 . Similar results were obtained using unit counting areas of $10\text{-}\mu\text{m}^2$ and $100\text{-}\mu\text{m}^2$.

of QNB during autoradiography appears to have occurred. Preparations which are incubated in ^3H -QNB in the presence of 100 nM unlabelled QNB have grain densities which are not different from background (Fig. 2c) except near the ends of cut fibres.

As silver grains are produced by random radioactive decay, a uniform distribution of QNB binding sites on the fibre would show as a random distribution of silver grains in the autoradiograph. To determine whether silver grains were randomly distributed, grains were counted in $25\text{-}\mu\text{m}^2$ areas of the muscle fibre. A frequency-grain count histogram was constructed and compared to the Poisson distribution expected if grain distributions were random. Figure 3 shows that grain distribution closely approximates a Poisson process (χ^2 goodness of fit shows that the observed and expected distributions are not statistically different ($P < 0.02$)).

Muscarinic ACh receptors in the heart function to decrease the force and rate of spontaneous contraction. To be effective, therefore, the action of ACh must extend over several cycles of the beat. Purves¹⁸ has pointed out that the slow kinetics of the muscarinic response is well suited for temporal summation and continuity of ACh action over several cardiac cycles. Further, I propose that the effective modulatory influence of ACh requires spatial continuity of ACh action; that is, because probably every cell in the sinus venosus and atrium can be a pacemaker cell, focal application of ACh to a small region would be ineffective in modulating overall heart rate or force. The diffuse pattern of innervation and uniform distribution of ACh receptors is ideally suited for spatial continuity of ACh action. The arrangement of presynaptic release sites is such that transmitter is in effect 'bath applied' to the muscle and the target responds to transmitter over its entire surface. Also, the slow time course of ACh action may be due in part to diffusion of transmitter across the receptor-populated surface of the muscle.

I thank Jan Zwemer for technical assistance, Joe Beahar for discussions and supplies and Mike Letinsky for details of his ZIO staining procedure. Supported by NIH HL21195 and Research Career Development Award HL00435.

Progesterone derivative binds to cardiac ouabain receptor and shows dissociation between sodium pump inhibition and increased contractile force

DIGITALIS and related steroid glycosides exert two well established actions: augmentation of the contractile force of cardiac muscle, the basis for the clinical use of these drugs; and inhibition of Na-K-ATPase, a ubiquitous membrane enzyme concerned with maintenance of transcellular ionic gradients. There is much evidence to support the disputed view that the inotropic effect of the cardiotonic steroids is a direct result of Na-K-ATPase inhibition^{1,2}. In a previous study³ a large number of steroids, drugs and other substances were screened for potential activity in a radioreceptor assay for cardiac glycosides. High affinity saturable binding of ^3H -ouabain to a particulate fraction from dog heart was highly specific and antagonised only by cardioactive glycosides or their aglycones and certain steroids related to hydroxyprogesterone. The most potent progestins active in the binding assay shared certain structural features: a 17α -acetoxy moiety and unsaturation or substitution in the B ring. Of the 17α -acetate progestins available for testing in the radioreceptor assay, chlormadinone acetate (CMA), 3,5-diene-3-one- 17α -ol-6-chloro-pregn-17-acetate, was the most active. In this report we describe results of studies with CMA designed to ascertain other potential digitalis-like actions. Digitalis-sensitive processes include ion and sugar flux in rat hemidiaphragm⁴ and guinea pig atrium⁵ and Na-K-ATPase activity in several tissues⁶.

In the radioreceptor assay CMA is about 1/50th as potent as ouabain in displacing specifically bound ^3H -ouabain (Fig. 1). (If inorganic phosphate is used in place of ATP + Na^+ in the assays, CMA is about 1/20th as potent as ouabain.) Several related progestins, medroxyprogesterone acetate, megestrol acetate, and cyproterone acetate were 4-10 times less potent, whereas progesterone and 17α -hydroxyprogesterone acetate were about 100 times less potent than CMA. All other steroids tested, including 17α -hydroxyprogesterone and a large number of 17α -substituted pregnanes, androstanes and estranes, were inactive.

In both beating and resting atria, concentrations of CMA ($0.5\text{-}5.0 \times 10^{-5}\text{ M}$) markedly increased internal Na^+ , indicating inhibition of the Na^+ pump (Fig. 2). Lower concentrations had a slight stimulatory effect on the pump, reflected in lower Na^+ levels. Changes in internal K^+ (not shown) were reciprocal to those in Na^+ concentrations. The same biphasic pattern has been described for ouabain in cardiac^{5,6} and skeletal muscle^{4,7}. The biphasic effect of CMA on the influx of the non-metabolised glucose analogue, 3-O-methyl-D-glucose (Fig. 2) was also

Fig. 1 Competitive binding of steroids in a ^3H -ouabain (11 Ci mmol^{-1} , Amersham) radioreceptor assay. *a*, Chlormadinone acetate (Lilly); *b*, megestrol acetate; Prog, progesterone; Preg: pregnenolone. Fresh or frozen heart ventricle from adult male dogs was minced with scissors and 20 g homogenised in a Polytron for 1.5 min in 160 ml of 10% sucrose in 10 mM Tris-HCl buffer, pH 7.4. The homogenate was filtered through a $210 \mu\text{m}$ nylon mesh screen and centrifuged at $110,000g$ for 30 min. The pellet was suspended in 160 ml of sucrose-Tris buffer, stirred for 1 h at 4°C and recentrifuged as above. The pellet was resuspended in buffer and used immediately or stored frozen in convenient aliquots. The buffer is slightly modified from that used by Schwartz *et al.*⁹ and contains 150 mM NaCl, 1 mM EDTA, 1.25 mM MgCl_2 and 50 mM Tris-HCl buffer (pH 7.4); ATP to yield a final concentration of 1.25 mM was added just before use. Competing test substance or unlabelled ouabain in 0.1 ml was mixed with 0.1 ml ^3H -ouabain in buffer to yield 9 nM of label, 0.6 ml buffer and 0.2 ml of freshly prepared or frozen suspension equivalent to 12.5 mg tissue wet weight and incubated at 37°C for 60 min with shaking. Incubation was terminated by rapid cooling of the assay tubes in an ice bath and centrifuging at $2,700g$ for 20 min. The resulting supernatant containing unbound ^3H -ouabain was discarded by aspiration. The membrane pellet was dissolved in 0.3 ml of 2M KOH by heating in a 70°C water bath for 10 min, and 0.2 ml transferred to a vial containing 10 ml of scintillation medium for ^3H counting. Steroids were insoluble in the buffer and were dissolved and diluted in ethanol. In the latter case incubation medium was added to the tube and vortexed after evaporation of the ethanol under a nitrogen stream. Unlabelled ouabain was added in the same way. Reproducibility of results with actively competing steroids indicated that the compounds were taken up by the buffer phase. Identical results were obtained in a few experiments where the alcohol stock solution was added directly to the incubation medium.

analogous to the effect of ouabain in resting atria reported previously^{5,6}. Sugar transport in resting muscle has been shown to vary in parallel with the intracellular level of sodium⁴⁻⁶ which governs Ca^{2+} influx by sarcolemmal $\text{Na}^+-\text{Ca}^{2+}$ exchange, and to reflect, therefore, the activity of the Na^+ pump. However, sugar transport is also affected by Ca^{2+} fluxes accompanying muscular contraction⁸ and depends on the rate and force of myocardial contraction. Accordingly, in beating atria the inotropic effect of ouabain is paralleled by a large rise in sugar transport⁶ (Fig. 2, broken line) which peaks at the concentration causing maximal inotropic effect ($0.5\text{--}1.0 \times 10^{-6} \text{ M}$). In contrast, CMA elicited no such contraction-dependent rise, and its effect on sugar transport in beating atria was like that in resting muscles and paralleled the changes in internal Na^+ . The effects of CMA on sugar transport are thus consistent with a lack of inotropic effect, together with a digitalis-like effect on the sodium pump.

In microsomes from guinea pig brain, CMA inhibited Na-K-ATPase, but not Mg-ATPase, 95% inhibition occurring at $4 \times 10^{-4} \text{ M}$. CMA was tested for potential inotropic activity on six isolated guinea pig atria at concentrations from 10^{-9} to $5 \times 10^{-5} \text{ M}$. In no instance was there any increase in contractile force; at high concentrations a decrease in contractility was

usually noted. In contrast, ouabain at $5 \times 10^{-7} \text{ M}$ consistently enhanced contractile force severalfold, the effect becoming apparent within 2 min and increasing over the 3-min observation period. In Fig. 3 typical records show that CMA neither exerted an action of its own on the beating heart nor interfered with the inotropic action of ouabain. In a separate series of experiments, cyproterone acetate also failed to affect contractility but consistently inhibited the pump.

Thomas *et al.*¹¹ reported a lack of strict proportionality between Na-K-ATPase inhibition and cardiotoxic activity of

Fig. 2 Effect of CMA on internal Na levels and sugar transport in guinea pig atria. ●, Resting atria; ○, beating atria, 75 min^{-1} . Isolated guinea pig left atria were prepared and perfused as described¹⁰ with ^{14}C -labelled 3-O-methyl-D-glucose (5.0 mM), tracer amounts of ^3H -inulin and CMA in the concentrations indicated on the abscissa. The ordinates show, respectively, per cent equilibration of 3-methylglucose in the intracellular water space, reached after 15 min perfusion, and intracellular concentration of Na^+ , determined by flame photometry, at the end of perfusion; both values were corrected for inulin space. Tissues were exposed to CMA for 15 min before and during perfusion with sugar. Stock solution of CMA in 95% ethanol was added dropwise to the buffer containing 4% 'fatty acid-free' serum albumin (Sigma). Concentrations of CMA in the buffer up to 10^{-4} M yielded clear solutions which were then used to replace the total volume of the organ bath. The final ethanol concentration was 0.13% and appropriate vehicle controls produced no detectable effects. Radioactivity was determined by liquid scintillation spectrometry¹⁰. Vertical bars indicate $\pm \text{s.e.m.}$ For comparison, effects of ouabain in beating atria are included (Δ) (redrawn from ref. 6). Statistical analysis (Student's *t* test) sugar transport: increased in beating against resting ($P < 0.01$) at all concentrations up to $5 \times 10^{-7} \text{ M}$ CMA; decreased at $5 \times 10^{-9} \text{ M}$ against control in beating ($P < 0.02$) and resting ($P < 0.001$). Increased at $5 \times 10^{-7} \text{ M}$ against $5 \times 10^{-9} \text{ M}$ in beating ($P < 0.005$), and against $5 \times 10^{-9} \text{ M}$ or control in resting ($P < 0.001$). Na^+ content: increased against control at $5 \times 10^{-8} \text{ M}$ ($P < 0.05$) and all higher concentrations ($P < 0.001$) in beating and at $5 \times 10^{-7} \text{ M}$ ($P < 0.02$) and $5 \times 10^{-6} \text{ M}$ ($P < 0.001$) in resting. No significant difference between resting and beating at any concentration.

Fig. 3 Contractility of the isolated guinea pig atrium as affected by ouabain and CMA. The left atrium of male guinea pigs was suspended (resting tension 1.5 g) at 37 °C in a 10-ml bath containing Krebs-bicarbonate buffer, pH 7.4, bubbled with 95% O₂/5% CO₂, and isometric contractions recorded on a polygraph with the use of a Grass force-displacement transducer. The atrium was stimulated at 2–3 Hz, 15 V, pulse duration 0.2 ms. CMA was added to the bath in a few μ l of ethanol, dimethyl sulphoxide, or Cremophore El (Sigma) with appropriate controls. The steroid was also solubilised in albumin-containing medium, in which CMA consistently inhibited the sodium pump.

some digitaloid derivatives. Our findings with CMA extend this to demonstrate complete lack of cardiotonic activity in a compound which significantly inhibits Na-K-ATPase in broken cells and Na⁺ pumping in intact cells and, moreover, competes with ouabain for specific binding sites. The data on sugar transport, serving as indicator of Na⁺ pumping and contractile activity, further support this dichotomy. These results indicate that sodium pump inhibition, even of the highly specific 'digitaloid' type, does not necessarily lead to increased contractility of cardiac cells. Furthermore, pump inhibition by CMA presumably occurs as a consequence of binding to the digitalis acceptor sites on the enzyme. This conclusion is based on the observation that CMA can displace practically all of the specifically bound ³H-ouabain, including, presumably, that portion of the cardiac glycoside which binds to and inhibits Na-K-ATPase.

The failure of CMA to antagonise the cardiotonic action of digitalis suggests that the progestin does not compete with digitalis at receptor sites coupled to events leading to increased contractility. Thus, only a very small proportion of digitalis specifically bound to cardiac membranes seems to be concerned with cardiotonic functions. It is proposed that digitalis binds with high affinity and high specificity to certain species of binding acceptor sites, also accepting active progestins, and including sites on Na-K-ATPase. In addition, digitalis may combine with another site, having little or no affinity for the progestins but concerned with the inotropic response.

Do laser diffraction studies on striated muscle indicate stepwise sarcomere shortening?

ILLUMINATION of striated muscle with a laser beam and measurement of the ensuing diffraction angles is a widely used method for the determination of sarcomere lengths. Pollack *et al.*¹ recently presented results showing that during internal shortening of single muscle fibres the angle of the diffracted first order beam changes in stepwise fashion. As the most likely explanation for this finding they suggested that the majority of the sarcomeres in the field illuminated by the laser beam, after having started shortening, suddenly cease shortening for several milliseconds before continuing the shortening process. The authors point out that this possibility would impose serious complications on the cross-bridge theory as presently envisaged^{2,3}, and in fact, on any proposed molecular theory of contraction. On the basis of diffraction studies using an experimental arrangement similar to that of Pollack *et al.* we now propose that the steps in the records of sarcomere length during contraction are an expression of slight differences in sarcomere length existing in myofibrillar clusters within the muscle fibre and therefore do not conflict with present contraction theories.

The intensity of light diffracted by striated muscle is strongly dependent on the angle ω between the beam of incident light and the fibre axis. This can be shown by rotating a single frog skeletal muscle fibre around an axis perpendicular to the fibre axis and perpendicular to the axis of a 100- μ m wide HeNe laser beam (Spectra Physics Model 155, $\lambda = 0.6328 \mu$ m). During this rotation we recorded the intensity of diffracted light for each order at the respective diffraction angles using a photodiode (PIN 25, UDT Inc.). Figure 1 presents results from such ω -scans (from +15° to -25° at a speed of 2° per s) obtained with an anterior tibial fibre (diameter $\approx 120 \mu$ m) at striation spacings set to a mean of 2.0 μ m (a) and 2.6 μ m (b). The intensity of light diffracted in the first order to the left is represented by dotted lines, and that diffracted to the right by solid lines. Such spectra show a distribution of light intensity over a range of some 20° with a halfwidth of about 10°. Sharp lines are superimposed on the continuous intensity distribution. The number and position of these lines is different for each illuminated fibre site. In general, maximum intensity does not occur at normal light incidence ($\omega = 0^\circ$). This intensity behaviour of diffracted light can be explained with the assumption that even a single fibre is too big to act as a plane grating. Rather volume effects seem to determine the diffraction process⁴.

The A-I-band pattern of adjacent myofibrils is arranged in register so that segments of high and low refractive index provide the fibre with a three-dimensional lattice of one-dimensional periodicity. Light microscopy shows that the register is not perfect in two respects. First, the segments (or idealised: lattice planes) may be inclined at a small angle η against the plane normal to the fibre axis. Second, this angle of inclination is not the same throughout the fibre diameter and along the illuminated fibre length. The myofibrils are rather arranged in clusters of variable size whose planes are inclined at small angles to each other. Thus, the lattice of the fibre resembles that of an imperfect crystal.

Fig. 1 Intensity of light diffracted in the first order to the left (dotted lines) and to the right (solid lines) as a function of the angle ω between incident laser beam and muscle fibre axis (linear scales, relative units). Sarcomere length set to 2.0 μm in *a* and to 2.6 μm in *b*.

Light diffraction by an imperfect volume lattice can be described using the Bragg formalism⁵. Only those lattice planes contribute to the diffraction process for which the condition $2d \sin \theta = k\lambda$ is fulfilled (d , lattice constant $\approx$ sarcomere length; θ , glancing angle between incident light and lattice plane; k , order of diffraction, λ , wavelength of light). Therefore, with normal light incidence the diffracted light is not generated by all myofibrils illuminated by the laser beam, but only by the small proportion whose planes happen to be inclined against the fibre axis at the Bragg angle ($\eta = \theta$). The Bragg formalism allows the diffraction process to be regarded as if the incident light is 'reflected' from the lattice planes, and each set of planes is able to reflect the light to the left or right if the glancing angle is appropriately set. This is why spectra of corresponding left and right orders from the same illuminated field are very similar in shape. Corresponding lines from the same myofibrillar cluster can easily be correlated as in Fig. 1. The Bragg condition requires that their positions in a plot of intensity against ω be separated by twice the Bragg angle. From the separation of the line positions, therefore, the sarcomere length of the corresponding myofibrillar cluster can be calculated.

The above points have been extensively discussed in an earlier paper⁴, but we now present evidence that the separation of corresponding lines is not exactly the same for all lines in a left-right pair of spectra. The most likely explanation for this is that different myofibrillar clusters in the fibre do not possess the same sarcomere length. As indicated in Fig. 1*a*, the lines with the largest amplitude are 13° apart, corresponding to a sarcomere length $d = 2.03 \mu\text{m}$, while most other line pairs are 13.3° apart, corresponding to $d = 1.99 \mu\text{m}$. Similarly, at the longer sarcomere length in Fig. 1*b*, the line separation varies between 9.7 and 10.3°, corresponding to $d = 2.72$ and $2.56 \mu\text{m}$. In other fibres similar variations were found, and in general the variation was at least 0.1 μm at $d = 2.5 \mu\text{m}$. Variability of the sarcomere length can also be determined from the angular dispersion of diffracted beams and variations of the same order of magnitude (2–3%) have been reported^{6,7}. These variations were, however, so far assumed to be distributed over the illuminated fibre volume in a more or less random way. We stress that the diffracted beams when viewed on a frosted glass screen show a microstructure, as described by Cleworth and Edman⁶, as if composed of several beams which show little dispersion, but

which are diffracted at slightly different angles. This microstructure and the results obtained from ω -scans (Fig. 1) suggest that sarcomere length dispersion stems from differences in the sarcomere length in the various myofibrillar clusters which themselves have a much more homogenous sarcomere length.

When a muscle fibre shortens, the Bragg condition requires that left and right hand spectra move apart along the ω -axis (Fig. 1*b* $\rightarrow$ *a*). The spectra also change their shape in an unpredictable way because different myofibrillar clusters will happen to fulfill the Bragg condition as sarcomere length decreases. If during such shortening the incident beam is first diffracted by a cluster with shorter sarcomere length and at a later time by a cluster with longer sarcomere length, the length signal in a diffractometer will behave as if the fibre ceases shortening or even lengthens, although both clusters shorten. This is schematically indicated in Fig. 2 in which for the sake of clarity this effect is exaggerated. Further, the figure represents only two clusters, one initially of $d = 2.2 \mu\text{m}$ and with an inclination η of 8.3°, the other of $d = 2.4 \mu\text{m}$ and with $\eta = 7.9^\circ$. The Bragg condition requires $\theta = 8.3^\circ$ for 2.2 μm and $\theta = 7.6^\circ$ for 2.4 μm . Thus, only the shorter cluster can diffract and the diffractometer indicates 2.2 μm . When both clusters shorten by 0.1 μm leaving their inclination η unchanged, at the new sarcomere lengths the Bragg condition requires $\theta = 8.7^\circ$ for $d = 2.1 \mu\text{m}$ and $\theta = 7.9^\circ$ for $d = 2.3 \mu\text{m}$. Only the longer cluster can now diffract and the diffractometer indicates 2.3 μm , that is, a lengthening, although both clusters have shortened. In a sarcomere length-time plot such as those recorded by Pollack *et al.*¹ such transitions could appear as a cessation of shortening. The duration of this cessation is about 4 ms in their records. This would correspond to a difference in sarcomere length between clusters of about 0.05 μm and therefore is well within the range of differences that we found by rotating the fibre (Fig. 1). If the Bragg condition is fulfilled initially by a cluster with greater sarcomere length and later by one with smaller d , a transition will appear as an acceleration. Accelerated shortening also seems present in the records of Pollack *et al.*

Since for a given angle of laser beam incidence (such as $\omega = 0^\circ$) the first order beams to the left and right are diffracted by completely different myofibrillar clusters, transitions from one cluster to the other during shortening should be uncorrelated when recorded with the left and right first order beams. We have repeated the experiments of Pollack *et al.* with an apparatus described previously⁸, recording internal shortening alternately with the left and right beam (Fig. 3). Results from five subsequent twitches are superimposed to show reproducibility. Although the diffraction process used for the records in Fig. 3*a* and *b* occurs in the same fibre volume, the left beam consistently

Fig. 2 *a*, Schematic drawing of a muscle fibre having two myofibrillar clusters of different sarcomere length 2.2 (lower) and 2.4 μm (upper). The striations have inclinations η against planes perpendicular to the fibre axis of 8.3° (lower) and 7.9° (upper). Only the lower cluster fulfils the Bragg condition (for $\lambda = 0.63 \mu\text{m}$), therefore the diffractometer indicates a sarcomere length of 2.2 μm . *b*, Both clusters shorten by 0.1 μm leaving their inclinations unchanged. Now only the upper cluster fulfils the Bragg condition, therefore the diffractometer indicates 2.3 μm . For clarity all angles are doubled in the drawing.

Fig. 3 Records of the time course of sarcomere length during internal shortening of a frog semitendinosus fibre. Panels *a* and *b* were obtained from exactly the same fibre volume recording the left (*a*) and right (*b*) first order beam. Traces obtained from five subsequent twitches are superimposed.

indicates a lengthening while the right beam indicates an accelerated shortening at the same time, 8 ms after the stimulus (arrows).

Although our experiments do not exclude the possibility of stepwise sarcomere shortening, they allow an interpretation of the stepwise changes during shortening of the angle of the diffracted beams which does not impose complications on molecular theories of contraction. The results suggest that the determination of sarcomere length from diffraction angles is not as simple and unproblematic as often believed. In particular, the sarcomere length determined at $\omega = 0^\circ$ may not be at all representative for the majority of the illuminated sarcomeres.

Evidence for the low molecular weight nature of scrapie agent

THE nature of the aetiological agent of scrapie disease, a transmissible encephalopathy naturally affecting sheep and goats, remains a perplexing problem of fundamental biological importance. Recent studies on brain tissue from outbred Syrian hamsters infected with a strain originating from the Chandler strain of mouse-adapted scrapie have led to a report of a DNA component essential for scrapie infectivity as suggested by sensitivity to DNase¹. The data presented here describe a purification procedure resulting in scrapie infectivity which migrates during polyacrylamide gel electrophoresis as a defined area of infectivity in a region characteristic of low molecular weight nucleic acid. This electrophoretically migrating species of the scrapie agent retains the characteristic disease properties by intercerebral inoculation of crude hamster brain homogenates. Infectivity isolated from this region was resistant to treatment with a combination of SDS and proteinase K followed by

ethanol precipitation. These data support the suggestion that the scrapie agent may be an infectious low molecular weight DNA.

Bioassay and electron microscopic examination of post-ribosomal high speed supernatant (HSS) subcellular fractions from hamsters clinically affected with scrapie disease revealed substantial amounts of scrapie infectivity and an absence of discernible membrane structures². Furthermore, 10% of that infectivity remained in the supernatant fraction after centrifugation at 100,000g for 44 h in sucrose-free buffer. Many of the properties of the scrapie agent—thermal stability, resistance to UV irradiation, nucleases, and proteinases—have been attributed to the intimate association of the scrapie agent with host cell components³. Accordingly, scrapie infectivity in the relatively less complex HSS fractions was more sensitive to heat and UV irradiation than in membrane-rich fractions⁴. However, exposure of the HSS fractions to the more specific degradation of nucleases and proteinases resulted in no apparent loss of infectivity. These results suggest that while discernible membrane structures were no longer associated with the scrapie agent, complexes might still offer protection of scrapie infectivity.

In an attempt to partially purify scrapie infectivity from host-cell components, the HSS was sequentially precipitated with 20, 40, 60 and 80% ammonium sulphate. Bioassay data indicated that scrapie infectivity was associated with all precipitated fractions and that the scrapie specific activity was not increased with respect to protein (Table 1). However, similar procedures applied to purified nucleic acids suggested that precipitation with 20 or 40% ammonium sulphate might result in preparations with low concentrations of host nucleic acids (Table 2), thus increasing scrapie specific activity with respect to cellular nucleic acid.

The 0-40% ammonium sulphate precipitate was electrophoresed on cylindrical 2.2% polyacrylamide gels containing 0.5% agarose and 0.1% SDS for 2 h at 6 mA per gel⁵. Absorbance profiles at 260 and 280 nm were identical when either scrapie-infected or uninfected samples were electrophoresed (Fig. 1b). Bioassay of eluates from gel sections indicated that a significant fraction of the scrapie infectivity penetrated the gel matrix and migrated with a characteristic mobility (Fig. 1c). Scrapie infectivity from gel eluates has been shown to be resistant to degradation by RNases and proteinases but sensitive to DNases with a decrease in infectivity (LD_{50} per ml) of three log units¹. As the hamster-scrapie bioassay system is only sensitive to changes in 90% of the total infectivity resulting in a change of one log₁₀ unit, concentration of three log₁₀ units of scrapie infectivity in one region of the gel over that found in other gel regions indicated a substantial level of purification by electrophoresis.

These results suggest that scrapie infectivity may be associated with a population of complexes of heterogeneous size and composition, from which the putative minimal infectious unit could be released or purified by ammonium sulphate precipitation and polyacrylamide gel electrophoresis. Whether the separation of this form of the scrapie agent from the HSS was due to partitioning of an existing minimal form of the scrapie agent or to a salt-dependent release of scrapie infectivity is not yet known.

Table 1 Ammonium sulphate precipitation of scrapie infectivity from HSS fractions

Ammonium sulphate (% at 0 °C)	Scrapie infectivity (log ₁₀ LD ₅₀ per ml)	Specific activity (log ₁₀ LD ₅₀ per µg protein)
0	8.7	6.4
0-20	8.0	5.9
20-40	8.0	5.1
40-60	8.0	5.6
60-80	8.0	5.1
80 supernatant	5.5	3.9

Table 2 Ammonium sulphate precipitation of purified radioactively labelled nucleic acids

Ammonium sulphate (% at 0 °C)	Percentage of acid-precipitable counts rRNA	DNA and tRNA
0-20	11%	11%
20-40	18%	12%

60-80	100%	29%

Electrophoresis of tRNA, rRNA and the citrus exocortis viroid (CEV) as RNA molecular weight markers and fragments from a *Hae*III digest of ΦX174 (RF) as DNA molecular weight markers indicated that RNA molecules of 23,000–70,000 and double-stranded DNA molecules of 48,000–130,000 molecular weight migrated to the region from which high scrapie activity could be eluted (Fig. 1a). The small size of the scrapie agent suggested by the electrophoretic mobility is compatible with the estimated target size deduced from inactivation by ionising irradiation^{6,7} and a small DNA eluted from hydroxyapatite⁸. Nucleic acid markers of low molecular weight migrate in a similar way to that of scrapie infectivity; it must be cautioned that the scrapie preparation may not be assumed to be a purified nucleic acid, and that association of scrapie DNA with one or more macromolecules could affect the migration pattern.

The apparent low molecular weight and increased sensitivity to degradative treatment upon purification resemble the properties of viroids⁹, the pathogenic RNA molecules responsible for several plant diseases. However, application of procedures for the extraction of the citrus exocortis viroid¹⁰ to infected brain tissue have resulted in a complete loss of infectivity¹¹. Possible explanations for the loss of infectivity are (1) that the nucleic acid must be associated with another component in order to be infectious, (2) that the nucleic acid is infectious, but only at low levels, or (3) that recovery of the infectious nucleic acid is dependent on the extraction procedure.

To examine the nucleic acid nature of the scrapie agent and the necessity of auxiliary components further, scrapie infectivity eluted from section 3 of polyacrylamide gels (Fig. 1c) was incubated with 0.5% SDS and 50 µg ml⁻¹ proteinase K for the deproteinisation of DNA¹², followed by ethanol precipitation and bioassay. This procedure resulted in no loss of infectivity. Examination of the gel eluate fraction under the electron microscope has revealed no particles suggestive of conventional viruses. These data further support the suggestion that the agent responsible for scrapie disease may be an infectious low molecular weight nucleic acid.

However, the possibility that the infectious unit may be nucleic acid in association with another macromolecule to form a complex unlike the regular geometric structure of viruses cannot be excluded. A nucleosome-like structure composed of 140–200 base pairs of DNA in a 10–11S nucleoprotein complex might exhibit similar migration properties in polyacrylamide gel electrophoresis, as well as variable sensitivity to DNase. A model similar to the nucleosome with DNA surrounding a protein molecule might explain the resistance of scrapie infectivity to degradation by proteinases. A further parallel might be drawn to adenovirus-5 DNA which is infectious, but with a 100-fold lower efficiency of transfection than that of the native DNA-protein complex. This DNA-protein complex is excluded from entering agarose or agarose-acrylamide composite gels during electrophoresis, while pronase-treated DNA migrates characteristically¹³, as does scrapie infectivity.

Thus the electrophoretic mobility of the minimal scrapie infectious unit is characteristic of a low molecular weight molecule, possibly of a free nucleic acid. Definition of the exact size and structure must await detection of the scrapie agent by physical procedures.

We thank L. K. Grill, A. E. Karu and W. O. Dawson for helpful discussion, and Dave Reynolds for electron microscopy. These studies were supported by NSF grant GB 39605 (to J.S.S.)

Guanine nucleotides distinguish between two dopamine receptors

BEHAVIOURAL¹ and neurophysiological² data suggest the existence of more than one dopamine receptor in the brain³. Differences in drug specificity of the dopamine-sensitive adenylate cyclase and dopamine receptors labelled by the butyrophenones, ³H-haloperidol or ³H-spiroperidol, indicate that the cyclase and the binding sites may, in part, involve distinct receptors^{4,5}. Lesion studies directly demonstrate the existence of physically distinct dopamine receptors in the corpus striatum⁶. Kainic acid microinjections, which selectively destroy intrinsic neurones in the corpus striatum, almost totally deplete the dopamine-sensitive adenylate cyclase while producing only a 40–50% decline in ³H-haloperidol or ³H-spiroperidol binding. Most of the remaining ³H-haloperidol or ³H-spiroperidol binding is lost following cerebral cortex ablation, which removes a major neuronal input to the corpus striatum, indicating that these binding sites are localised to axons and terminals of the cortico-striate projection⁶. As the dopamine-sensitive adenylate cyclase is not reduced by cerebral cortex ablation, the cortico-striate dopamine receptors do not seem to be linked to adenylate cyclase. Whether or not the ³H-butyrophenone binding sites destroyed by kainic acid represent the same dopamine receptors as those linked to adenylate cyclase has not been clear. Guanine nucleotides regulate binding at several hormone and neurotransmitter receptors, especially those associated with adenylate cyclase^{7–13}. Previously, we^{14–16} and others¹⁷ showed that dopamine receptor binding of ³H-agonists and ³H-antagonists can be regulated by guanine nucleotides. We now report that kainic acid lesions abolish the sensitivity of dopamine receptor binding to guanine nucleotides. Thus, ³H-spiroperidol and ³H-apomorphine binding sites involve two dopamine receptors, only one of which is regulated by guanine nucleotides.

After anaesthesia with Equithesin (0.6 ml, Jensen-Salisbury), Sprague-Dawley rats (160 g) were positioned in a David Kopf small-animal stereotaxic apparatus and a 0.3-mm Hamilton cannula was inserted into the striatum through a burr hole in the calvarium (coordinates: 7.9A; 2.6L; 4.8V). Kainic acid (Sigma), 2 µg in 1 µl of artificial cerebrospinal fluid titrated to pH 7.4, was infused and the scalp was then apposed with sutures. Two to five weeks after kainic acid injection, the corpus striatum ipsilateral to the lesion and the contralateral unlesioned striatum, and striata from unlesioned animals were assayed for ³H-spiroperidol and ³H-apomorphine binding, essentially as previously described¹⁴. Freshly homogenised striata (100 volumes of 50 mM Tris buffer with 0.1% ascorbic acid, pH 7.1, at 30 °C disrupted with a sonicator) were centrifuged twice at 50,000g

for 10 min with rehomogenisation of the intermediate pellet in fresh buffer. The final pellet was resuspended in buffer mix (5 mg ml⁻¹). Incubation tubes in triplicate received ³H-apomorphine or ³H-spiroperidol, tissue suspension and buffer to 1 ml. Tubes were incubated for 10 min at 37 °C and then rapidly filtered under vacuum through Whatman GF/B filters with three 5-ml rinses of ice-cold buffer. The filters were counted in 9 ml Formula 947 (NEN) after 12 h extraction at 4 °C at efficiencies of 37–44%. Saturable or specific binding was measured as the excess over blanks containing 1 µM and 10 µM *d*-butaclamol for ³H-spiroperidol and ³H-apomorphine assays respectively. Blank values were 20% and 40% of total ³H-spiroperidol and ³H-apomorphine binding, respectively.

As reported earlier, GTP lowers the binding of the agonist ³H-apomorphine with an IC₅₀ of 5–10 µM (refs 14–16) (Table 1). GDP and Gpp(NH)p (the non-metabolised analogue of GTP) have the same potency in eliciting this effect, but GMP, ATP, ADP and AMP are completely inactive.

Fig. 1 The effect of striatal kainate lesion on GTP alteration of the potency of dopamine in competing for striatal ³H-spiroperidol binding. Each point is the mean of 10 determinations. Solid lines, control; dashed lines, kainate lesion.

GTP does not reduce the total binding of the antagonist ³H-spiroperidol. However, as found previously, GTP decreases the dopamine inhibition of ³H-spiroperidol binding^{14–17}. The IC₅₀ concentration for dopamine (2 µM) is increased about threefold (to 6.4 µM) in the presence of 50 µM GTP. This effect is specific in that it is exerted with the same potency by GDP and Gpp(NH)p but not by GMP, ATP, ADP or AMP. However, inhibition of ³H-spiroperidol binding by antagonists such as fluphenazine and haloperidol is unaffected by GTP¹⁶.

Kainic acid lesions, in conditions which destroy intrinsic striatal neurones as verified by biochemical and anatomical examination in this laboratory⁶, but which spare glia and neurones whose cells originate in other brain regions, reduce specific ³H-spiroperidol binding by 54 ± 3%. In lesioned animals dopamine is 4–5-fold less potent an inhibitor of ³H-spiroperidol binding than in control animals. However, the residual binding after kainate lesions still involves dopamine receptors, as drug specificity studies indicate a greater potency for dopamine than for noradrenaline or serotonin in inhibiting ³H-spiroperidol binding, and isoprenaline is inactive.

Strikingly, after kainate lesion, GTP no longer affects the potency of dopamine as an inhibitor of ³H-spiroperidol binding (Fig. 1). This loss of effect of GTP suggests that the residual binding involves a distinct dopamine receptor site which is not regulated by guanine nucleotides. To ascertain whether two such distinct dopamine receptors were labelled by ³H-agonists,

Table 1 Kainate lesion abolishes influence of GTP on striatal ³H-apomorphine binding

	³ H-apomorphine binding (pmol per g tissue wet weight)	
	Unlesioned side	Lesioned side
– GTP	18.5 ± 0.46	6.62 ± 3.2
+ 50 µM GTP	9.90* ± 0.15	5.73 ± 2.5
% Reduction by GTP	47.0 ± 1	9.0 ± 5

Kainate lesions and ³H-apomorphine binding were carried out as described in the text. Data are means ± s.e.m. for groups of 3 rats. This experiment was repeated twice in groups of 3–4 rats each. Per cent reduction data were determined by computing for each rat the ratio of binding in the presence and absence of GTP.

* Differs from unlesioned side without GTP $P < 0.001$

we evaluated the binding of ^3H -apomorphine (Table 1). GTP ($50\ \mu\text{M}$) reduces ^3H -apomorphine binding in normal rats by 47%, but no longer does so following kainate lesion, which lowers specific ^3H -apomorphine binding to 36% of control. Thus, following kainate lesions both residual ^3H -apomorphine and ^3H -spiroperidol binding is resistant to GTP.

Thus, we have found that guanine nucleotide regulation of both ^3H -agonist and ^3H -antagonist binding to dopamine receptor is lost following kainic acid lesion. This suggests that the dopamine receptors contained on the intrinsic neurones destroyed by kainic acid are regulated by guanine nucleotides, whereas those localised to the cortico-striate neurones are not. As guanine nucleotides regulate binding of receptors linked to adenylate cyclase and as the dopamine cyclase is also contained on intrinsic neurones, we conclude that the ^3H -spiroperidol and ^3H -apomorphine binding sites contained on the intrinsic neurones destroyed by kainate may involve the cyclase-linked dopamine receptors referred to as D-1 dopamine receptors^{17,18}. The notion that the cyclase-linked dopamine receptor is regulated by GTP is supported by the direct demonstration of GTP influences on the dopamine-sensitive adenylate cyclase of striatal homogenates¹⁹. By contrast, the cortico-striate dopamine receptors are not linked to adenylate cyclase and may be designated D-2 dopamine receptors.

The drug specificity of ^3H -spiroperidol binding differs from that of the dopamine-sensitive adenylate cyclase. Previously, we proposed that ^3H -agonists and ^3H -butyrophenone antagonists label distinct agonist and antagonist preferring states of dopamine receptors⁴. We suggest that ^3H -spiroperidol and ^3H -apomorphine binding to intrinsic striatal neurones destroyed by kainate label distinct agonist and antagonist preferring states of the cyclase-linked dopamine receptors. This would account for the finding that the drug specificity of the ^3H -apomorphine binding sites resembles that of the dopamine-sensitive adenylate cyclase more closely than that of ^3H -spiroperidol binding¹⁴.

New type of twisted mesophase in jellies and solid films of chiral 12-hydroxyoctadecanoic acid

SOME optically active substances are known to form a unique state of matter, the twisted mesophase, in which a supramolecular helical structure gives rise to some striking optical phenomena¹. This type of structure was first found in melts of single compounds and later in solutions of some biopolymers. The only lyotropic twisted mesophases reported so far are the cholesteric (twisted nematic) type. However, we describe here a new type, found in the thermally-reversible jellies formed by chiral 12-hydroxyoctadecanoic acid (12HOA) with CCl_4 or aromatic solvents; solid films obtained by drying the jellies on quartz supports retained the twisted structure. Microscopy and circular dichroism (CD) indicated that this mesophase had a supramolecular helical structure, and X-ray examination of the dried solid films indicated that it was not a nematic type, but probably smectic.

Crystalline samples of 12HOA were prepared as described previously². Solutions of chiral 12HOA in CCl_4 set to an almost transparent jelly above $13\ \text{mmol l}^{-1}$ at 20°C , while solutions of racemic 12HOA showed no gelation until they deposited crystals from a saturated solution. The thin preparations of the jellies observed under crossed polarisers in a polarising microscope exhibited a birefringent pattern with a spherulitic or Schlieren texture of the sort observed for some liquid crystals. This characteristic appearance suggests that the jellies are a lyotropic mesophase.

The jellies exhibited a weak but definite CD in a range of wavelengths in which they absorbed no light, and the sign was negative for the D-enantiomer and positive for the L-enantiomer, irrespective of solvents used. Figure 1 shows a typical

Fig. 1 Enantiomeric CD bands of jellies of 12HOA- CCl_4 ($25.7\ \text{mmol l}^{-1}$ for the L acid, $35.7\ \text{mmol l}^{-1}$ for the D acid). These spectra were measured using a 10 mm-thick cell on a JASCO J-20A spectropolarimeter at room temperature. The location of the CD maximum was dependent on solvents (for example 350 nm for CCl_4 , 480 nm for benzene), but insensitive to change of temperature. The intensity and the location of the peak varied slightly for different samples.

example of the enantiomeric CD bands for jellies of D- and L-12HOA. Little linear dichroism was observed when jellies were examined by the procedure of Tunis-Schneider and Maestre³. Therefore we ascribed the observed CD to the preferential reflection of circularly polarised light of one sense by the jellies. The same optical phenomenon¹ has been observed for cholesteric liquid crystals and explained by assuming a supramolecular helical structure with the twist determined by the chirality of the constituent molecules.

Enantiomeric induced CD (ICD) could also be observed for some achiral molecules dissolved in jellies of chiral 12HOA. Figure 2 shows the ICD bands (superimposed on the CD curve of the jelly) and electronic spectra between 330 and 395 nm for anthracene dissolved in a jelly of D-12HOA. Interestingly, the ICD bands show a single sign and follow closely the electronic spectral bands; such ICD characteristics have been obtained for lyotropic cholesteric mesophases of poly- γ -benzyl-L(or D)-glutamate (PBG)⁴ and other polypeptides, and more recently for those of *N*-acylamino acids⁵.

In view of these CD and ICD results, it is possible that a supramolecular helical structure exists in jellies of 12HOA. Then the 350 nm CD band maximum would correspond to the 'pitch band' and the observed ICD would be caused by the dissymmetrical field of the helical structure, although it is weak compared with the effect in cholesteric systems⁴. This proposed helical structure is associated with the jelly structure in which hydrogen bonding is involved⁶, because melting of the jelly by heating resulted in the loss of all the optical properties mentioned above.

We found that all the optical phenomena described here manifested themselves more clearly in thin semi-transparent solid films (about 50 μ m) obtained by drying jellies of chiral 12HOA on quartz supports. When the films were dried, the CD increased in intensity and the peak was shifted to the shorter wavelength side. These results indicate that the original supramolecular helical structure in jellies is fully retained in such solid films. Similar behaviour has been found with the cholesteric mesophase of polypeptides⁷.

Microscopy with a controlled hot stage showed that, when such solid films were heated, the mesomorphic texture became obscure at about 348 K, and then needle-like microcrystals formed: CD was no longer observed. Finally the microcrystals melted at 353 K (melting point of chiral 12HOA).

X-ray diffraction patterns for these solid films obtained by drying were similar to those for the crystalline powder, although slightly more broad. A long spacing of 46.7 Å was obtained and interpreted as the distance between double plane layers of amphiphilic molecules of 12HOA. This suggests that the mesophase structure retained in these solid films, and possibly also the structure of the mesophase itself, is not nematic, as has been shown for the cholesteric mesophase of PBG, but smectic. In the layer structure with a twisting, the molecular long axes would have to be tilted relative to the layer planes. The length of the crystallographic *c* axis of octadecanoic acid which is an analogue of 12HOA, that is, the extended length of the bimolecule, has been reported to be 49.38 Å for the B form⁸ and 50.7 Å for the C form⁹. These values are greater than 46.7 Å. This result supports the tilt possibility. It was impossible, however, to prepare orientated samples of jellies and solid films which exhibited regularly-spaced retardation lines or iridescent colours like those observed for the cholesteric mesophase of polypeptides. It seems reasonable to consider that the twisted mesophase structure exists locally as small domains which disperse with randomly-orientated helical axes within jellies or solid films. This would explain the small size of the observed CD band compared with the effect in cholesteric mesophases.

Electron microscopy has shown that both chiral 12HOA (ref. 2) and PBG (ref. 9) formed by precipitation from certain solvents produce helically twisted fibrils with handedness determined by the chirality of the molecule. Because biologically important molecules are essentially chiral, it may be biologically significant that some chiral molecules form helically

Fig. 2 a, ICD spectral bands (—) for anthracene (8.8 mmol l^{-1}) superimposed on the CD curve (---) of the jelly (D-12HOA- CCl_4). b, Electronic spectra of anthracene. Enantiomeric ICD bands were obtained for a jelly of the L acid. On addition of anthracene, the CD maximum of the jelly itself was shifted to the longer wavelength side ($\sim 450 \text{ nm}$).

organised systems in different stages, as has been shown for 12HOA and polypeptides.

Erratum

In the letter 'Maximum density of random placing of membrane particles' by L. Finegold and J. T. Donnell, *Nature* **278**, 443-445, the bottom line of the legend to Table 1 should be included in the table under 'Circular particles'.

Corrigendum

In the letter 'Deficient production of tyramine and octopamine in cases of depression' by M. Sandler *et al.*, *Nature* **278**, 357-358, the units of the third column of Table 2 should read nmol instead of μ mol.

matters arising

Origin of the Metazoa

THE recent article by LaBarbera¹, in which the late Precambrian appearance of multicellular organisms is related to the development of shallow-water marine environments late in the Proterozoic, requires some examination of the evidence from which his conclusions have been drawn. LaBarbera bases his arguments on Hargraves² model for the evolution of the Earth through the Precambrian. Hargraves' model has been shown by Windley³ to be totally incompatible with the geological evidence as it relates to processes taking place on the Earth's surface.

LaBarbera's statement that "during the first three-quarters of the Precambrian . . . , shallow water environments (defined here as less than 200 m depth) were very rare, and those that did exist were the result of volcanic or dynamic mountain-building processes and were geologically transitory" cannot stand unchallenged.

While it can be argued that, apart from the 3,000 Myr Pongola sequence⁴, most shallow-water environments recognised in Archaean sediments⁵⁻⁹ may have been geologically transitory, it cannot reasonably be disputed that from about 2,500 Myr ago, shallow-water environments occurred frequently, were developed extensively and were geologically persistent. Examples are too numerous to list here¹⁰, but a few outstanding and clearly documented cases from the Early and Middle Proterozoic from widely separated areas are the sediments of the Athapuscow Aulacogen¹¹ and Kilohigok Basin¹² of Canada, the Transvaal Basin of South Africa¹³, and the Nabberu¹⁴ and McArthur Basins^{15,16} of Australia. All the major Proterozoic basins contain stromatolitic carbonate sediments, most of which are interpreted as being of shallow-water marine origin¹⁷. Thus LaBarbera's comment that the shallow-water fossils "are restricted to a surprisingly few localities" cannot be sustained. Furthermore, these basins frequently contain additional sedimentological evidence which, taken together, indicates deposition in shallow-water environments; for example, numerous breaks in sedimentation, with desiccation, formation of evaporites¹⁵, oolitic, pisolitic and intraclastic beds, and

tidal channel and associated continental marginal deposits. In fact, in the Proterozoic record, it is deep-water sediments that are rare, and not shallow-water ones.

A further point which must be challenged is LaBarbera's contention that early life evolved in deep-water environments, and that its most primitive manifestations must have been planktic. However, the assemblages¹⁸ which he quotes as being the "fossil record for most of the Precambrian" are all associated with stromatolitic carbonates, and they are all benthic. The organisms lived at the sediment-water interface, or just below it, and trapped or precipitated carbonate sediments by their metabolic activities. Some of the described microfossils may have had a planktic phase in their life cycle, or isolated species (for example, *Eosphaera*¹⁹ from the Gunflint Iron Formation, Canada) may have lived in surface waters—but in all cases, the water depth was shallow to very shallow. Clear evidence for oceanic microplankton appears only in the latest Precambrian.

Two recently described assemblages from Middle Proterozoic shales^{20,21} contain large spheres that may be planktic; but petrographic and palaeogeographic studies show these shales to be products of shallow-water environments. It should be added, however, that oceanic plankton has poor preservation potential in deep water unless it has very chemically resistant walls²².

Thus the major point that LaBarbera had hoped to demonstrate for the evolution of multicellular organisms is geologically untenable. A number of other recent models²³⁻²⁷ are more compatible with the geological evidence.

LABARBERA REPLIES—Muir, Walter and Jackson (and others¹) have apparently misinterpreted the purpose of my article² despite the explicit statement in the first paragraph that it was an "attempt to evaluate some of the implications of Hargraves' model of the geophysical evolution of the Earth during the Precambrian for the evolution of the metazoan phyla". The statement cited by Muir *et al.* concerning the existence of shallow-water environments through much of the Precambrian was not my conclusion, although failure to quote the entire sentence from my article makes it sound as though it were (missing from their quote is the phrase, "The primary implication of Hargraves' model is that . . .").

Muir *et al.* take two other quotes out of context, and by doing so change their original meanings. The complete relevant section reads, "The fossil record for most

of the Precambrian is restricted to algal stromatolites and associated microfossils which are acknowledged to be of shallow water origin. However, these fossils are restricted to a surprisingly few localities...". Nowhere do I either state or imply that Precambrian deep-water deposits are common in an absolute sense or more common than Precambrian shallow-water deposits. Nor, as is obvious from the full quote, do I deny the shallow-water origin of stromatolites. The point of this section (perhaps too tersely made) was that one cannot presume full knowledge of the history of life on an entire planet over approximately 3,500 Myr when the fossil evidence is restricted to a single (shallow-water) environment from approximately 30 sequences³.

My article² was not a defence of Hargraves' model⁴ but an exploration of some of its implications. I welcome the contributions of Windley⁵ and Knoll⁶, who have attempted to separate fact from fancy, to this discussion. However, the extent to which Hargraves' model is applicable to Precambrian geological history is still being evaluated^{7,8} and some observations^{8,9} have yet to be adequately explained in the context of more traditional models.

Mutagenesis of Chinese hamster cells is facilitated by thymidine and deoxycytidine

THE presence of thymidine and/or deoxycytidine in cell cultures has been reported by Peterson *et al.*¹ to modify the mutagenic potential of methylation by *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine. It has long been proposed that *O*⁶-alkylguanines are potential promutagenic lesions in alkylated DNA² and this has been supported by *in vitro* experiments with bacterial RNA polymerase³. From our own *in vitro* experiments⁴ using *Escherichia coli* polymerase I acting on methylated poly(dC-dG) templates, we have concluded that any miscoding (that is, mutations, shown by the incorporation of dTMP) arising from the presence of *O*⁶-methylguanine in the template is

competitive with the normal (correct) incorporation of dCMP. Furthermore, the amount of miscoding observed depends on the relative concentrations of the DNA precursors dTTP and dCTP used in the assay. Such competitive miscoding by *O*⁶-methylguanine leads to the possibility of an alteration in the level of miscoding by factors which influence the size of the deoxynucleoside 5'-triphosphate DNA-precursor pools within the cell. It is therefore possible that agents which alter the size of these pools may enhance, or reduce, the mutagenic potential of alkylating agents. Although factors governing mutation within cultured mammalian cells are extremely complex, we believe that our observations may in part explain the results obtained by Peterson *et al.*

Synergistic chelation therapy or mixed ligand complexes for plutonium and cadmium poisoning?

PROGRESS in the development of chelating therapeutic drugs has been disappointing, especially when one considers the variety of diseases which respond to trace element regulation¹. The unparalleled success of two simultaneously administered ligand drugs at eliminating plutonium, reported by Schubert and Derr², is therefore most impressive.

Conceptually, the use of such double ligand treatment is not new; it has been advocated for the removal of both lead³ and copper⁴. However, Schubert's remarkable biological data emphasise the need to understand how a combination of chelating agents act. We suggest that there are alternative explanations besides the formation of mixed ligand complexes proposed in ref. 2, in which both drugs are complexed on to the metal ion.

In this context, biological transport is by passive diffusion⁵ so there are at least six requirements, which a chelating agent must ideally satisfy. It should (1) bind the metal strongly enough to compete with biological ligands, especially proteins; (2) discriminate against the relatively abundant calcium and zinc cations *in vivo*; (3) be sufficiently lipophilic to penetrate membranes and hence reach the site of

heavy metal deposition; (4) form a lipophilic complex in the body compartment where the metal has accumulated; (5) change to a hydrophilic complex in plasma so the metal is eliminated in urine, not redistributed into other tissues; (6) have a low toxicity (this has implications for each of the preceding requirements).

A single ligand cannot easily meet these conditions, particularly those dealing with lipophilicity. For example, the commonly used polyaminocarboxylic acids are confined to extracellular space and rely on naturally occurring ligands to leach the poisonous metal out of the tissues^{2,5}. On the other hand, two dissimilar drugs can be chosen to satisfy collectively all the above-mentioned requirements. Synergistic chelation therapy occurs when one drug mobilises the metal while the other traps it in plasma to be excreted in the urine.

Low molecular weight transition metal complexes in biological systems almost always occur at concentrations well below the level of analytical detection⁶. Thus, we advocate that computer simulation studies of speciation in biological fluids^{2,6} be extended to plutonium and cadmium to establish whether Schubert's drugs bind to the metal ion simultaneously *in vivo* as he suggests, or whether they function separately.

SCHUBERT AND DERR REPLY—The use of double ligand therapy for decontamination of metals and therapy of metal poisoning is discussed in several references cited in our necessarily brief report. Combinations of chelating agents for decontamination were used in Hamilton's laboratory at Berkeley¹ assuming, as is usual^{2,3}, that pharmacokinetic differences would produce enhanced effects. In some instances, mixed ligand chelates which might have formed were either too weak and/or used chelants readily metabolised, such as citrates³. The results we aimed for and achieved⁴, required deliberate use of chelant combinations which form mixed ligand chelates with stabilities orders of magnitude greater than single chelants. From

the known chemistry of mixed ligand chelate formation, as we describe elsewhere⁵, the choice of suitable combinations is straightforward. For example, Martell *et al.*⁶ demonstrated, using potentiometric titrations, that Th(IV) formed very stable mixed ligand chelates with EDTA, salicylate and catechol (10^{11} – 10^{13} times more stable than EDTA alone). As expected, Pu(IV) reacted similarly.

We reject the suggestion, unsupported by experimental evidence, that alternative explanations besides mixed ligand complexes are responsible for our results. Our experiments^{4,5}, including ultrafiltration, solvent extraction, and *in vivo* reversal of salicylate antipyresis by Zn and Cu EDTA, provided experimental evidence for mixed ligand chelate formation. The proposed mixed ligand chelate of Pu with DTPA and salicylate is depicted by the following structure:

The requirements for biological transport emphasised by May and Williams have long been known. It is not necessarily true, however, that highly charged polyaminopolycarboxylic acids are confined to extracellular spaces. A very small but adequate fraction of these chelants penetrate intracellular space as shown by sustained excretion of metals following single treatment^{7,8}. Charged metal ions, for example, chromate, can also penetrate cell membranes and reach cell interiors⁹. May and Williams' proposal that synergistic chelation therapy occurs when one drug mobilises the metal and the other traps it in plasma is inapplicable to our systems, as compounds such as salicylate and catechol by themselves do not react with Pu(IV) in *in vivo* conditions.

Although computer simulation studies of speciation in biological fluids have a certain value, they are unnecessary in our therapeutic investigations, as even simple non-computer calculations readily show that the very strong mixed ligand chelates used by us bind >99% of the total metal. Indeed, this is shown in their own calculations¹⁰, even with single chelants, and computer calculations used previously¹¹ by one of us. The ability of complexing

agents to bind metals in the blood stream does not necessarily coincide with the ability to remove metals deposited in the tissues¹².

Evolution of the 3', 5' internucleotide bond

DHINGRA AND SARMA¹ posed the question "Why do nucleic acids have 3', 5' phosphodiester bonds?". They concluded from a detailed NMR investigation of the conformations of dinucleoside monophosphates that 2', 5'-linked oligomers are unlikely to form helical structures that are stabilised by base-stacking. Thus 2', 5'-linked nucleic acids would be less suitable for participation in present day biochemical operations that involve helix formation. Dhingra and Sarma considered a polymer as a set of repeating dimer structures and did not consider the perturbations that could be introduced by the presence of a complementary strand. There is, of course, evidence that 2', 5'-linked oligomers can complex with 3', 5'-linked complementary polymers, although the melting temperatures of these complexes do tend to be lower than in the case of an all 3', 5'-linked complex².

We considered this same question some years ago, and predicted³ that the 2', 5' bond in a helical oligonucleotide would be more susceptible to non-enzymatic chain breakage than would the 3', 5' bond. A large difference in kinetic stability was subsequently demonstrated experimentally for a triple helix of oligoadenylates and poly U in mildly basic solution⁴. Thus during the early chemical evolution of nucleic acids, it seems reasonable to suppose that there was a strong selective pressure for the 3', 5' bond, and against the 2', 5' bond.⁵

SARMA AND DHINGRA REPLY—Since the publication of our paper in *Nature* we have carried out extensive NMR studies in 100% water on self-complementary 2'5'-dinucleoside monophosphates, that is

to monitor the Watson–Crick hydrogen bonding protons. The data showed that 2'5'-linked dimers have little proclivity to form Watson–Crick hydrogen bonded miniature double helices under conditions in which their 3'5' analogues have been shown¹ to form such complexes. The study has revealed that the availability of a complementary dimer does not introduce enough perturbations to the intrinsic stereochemistry of 2'5' systems to induce the formation of miniature double helices. In this connection, it is important to note that in the reported crystal structure of 2'5' ApU no miniature double helices have been observed², contrary to the crystal structure findings on 3'5' ApU and 3'5' GpC^{3–5}, but like 3'5' UpA⁶.

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 300 words and the briefest of replies, to the effect that a point is taken, should be considered.

Perfect photo-micrography at the touch of a button.

With the Wild MPS-System.

The new Photoautomat from Wild Heerbrugg represents a tremendous stride in the recording of microscopy specimens; an assurance of optimal exposure, superlative imaging and planned work. Everything has been automated: camera factor change between formats from 35 mm to $4 \times 5''$; super-sensitive exposure measurement for films from 5 to 43 DIN; exposure corresponding to film emulsion, with or without correction for reciprocity failure; film transport. Just concentrate on the specimen and on composing an expressive format.

Press the button, and everything is taken care of. This doesn't mean that the Photoautomat jealously guards its secrets! The control unit displays not only the exposure time, but also the percentage of time elapsed, both of which can be influenced individually. That's how photomicrographs are made in series with the Wild MPS. Professional ones.

The various MPS systems for microscopes and stereomicroscopes are described in a colour leaflet. Ask for it.

Cosmic Dust

P. G. Martin

In this introduction to interstellar dust and its impact on astronomy the author concentrates on providing the tools and discussing the concepts which underlie current research, interweaving this with informed accounts of our present understanding and some suggestions for the future. He covers the fundamental ways in which dust is studied, examines the problem of determining the composition of the dust particles, and considers dust in other galaxies and in intergalactic space. Black-Body Theory and the Quantum Discontinuity 1894-1912

Thomas S. Kuhn

Here is a monograph on the development of quantum conditions, a central theme in the evolution of the quantum theory. It provides a strategic survey of the development of that theory, tracing Planck's route to the black-body problem through the classical phase to the breakdown of his theory and Einstein's new approach. An account of converts to discontinuity follows, and the book ends with Planck's new radiation theory. £12.50

Experimental Techniques in Low-Temperature Physics

Guy K. White

This book was written chiefly to help those physicists, physical chemists, metallurgists, and engineers who need to carry out investigations at low temperatures. It deals with the production and measurement of low temperatures, the handling of liquified gases on the laboratory scale, the principles and some details of the design of experimental cryostats, including the problems of heat transfer and temperature controls. Illustrated £15 *Monographs on the Physics and Chemistry of Materials*

Bibliography of Ab Initio Molecular Wave Functions

Supplement for 1974-1977

W. G. Richards, P. R. Scott,
E. A. Colbourn, and A. F. Marchington

This second supplement to the standard work of reference has been produced as a result of requests from users, and continues the chronological survey from 1 January 1974 to 31 December 1977. Each molecule or ion is treated separately; all publications are listed chronologically and are illuminated by brief annotations. Paper covers £17.50 *Oxford Science Research Papers*

Historical cetology

J. H. S. Blaxter

The Natural History of the Whale. By L. Harrison Matthews. Pp. 219. (Weidenfeld and Nicolson. London, 1978.) £12.50.

THE *World Naturalist Series* (not to be confused with the *New Naturalist Series*) continues with a book on whales by the editor of the series. There are nine chapters—on Cetology from its Beginnings, Cetacean Diversity, Food and Feeding, Breeding and Growth, Swimming and Diving, Migration, Communication and Echolocation, Behaviour and Social Relations, Parasites, Diseases and Enemies—followed by a list of living species, a bibliography and index.

The book is very readable and is especially strong on the historical aspects of research on whales. Unlike so many subjects where the older literature tends to become obsolete, modern cetology depends very much on the earlier work. One of the reasons for this lies, alas, in the appalling over-exploitation of whales, so that many species are protected and some may be near extinction. Thus, material, often available in the past only through the whaling industry, is no longer obtainable. The discoveries made have been impressive, especially when one considers the difficulty of handling such large specimens, the problem of rapid decomposition before they can be dissected and the need, often, to play 'second fiddle' to the whale-catchers. Much of the more recent discoveries on whale physiology and behaviour come from the smaller cetaceans such as the dolphins which are fairly easy to catch and keep in captivity. The building of oceanaria has also made it possible to watch and train larger cetaceans such as the Killer Whale. Speculation about echolocation, feeding habits, buoyancy mechanisms and the problems of deep diving have come from the study of so-called functional anatomy.

This all makes fascinating reading. Everything is on a massive or record scale. The blue whale is the largest living animal; whales make migrations of 28,000–30,000 kilometres and can 'sprint' at 20 knots; sperm whales can dive to 3,000 feet and become entangled in submarine cables; the Antarctic whales in their heyday ate 150 million tons of krill annually; some

whales have tape-worms which are 50 feet long!

I found the style of the book rather uneven. The author expects a fairly high standard of knowledge from the reader when discussing some of the anatomy, especially that of the skull, yet elsewhere, for example, he discusses the genetic code, DNA and the philosophy of immortality (pages 76 and 137). In general the diagrams, though clear, are inadequately labelled and have no scale given. There are 16 pages of black-and-white plates which cannot fail to fascinate the reader. One aerial photograph of a school of white whales in the Canadian Arctic showing adults and calves is especially interesting.

The author is decidedly acerbic about some of his predecessors and of some later investigators. On page 28 he gives very short shrift to *Nessiteras rhombopteryx* P. Scott (1975) the "non-animal of Loch Ness" (reported in *Nature* 258, 466, 1975). On page 101 he castigates the owners of pets who recycled whale meat as dog-droppings on city pavements. He is rightly uncompromising in his criticism of anthropomorphism in our interpretation of cetacean behaviour. For example, the explanation of the apparent saving of

human swimmers in distress by dolphins lifting them to the surface almost certainly lies in the lifting of newly-born calves by their mothers to the surface for their first breath of air. Other instances of relationships between cetaceans and man such as the riding of ships' bow-waves can easily be explained as advantageous to the animal, which saves energy as it utilises the bow-wave to push itself along. Although the author is not in possession of the results of naval research on the use of dolphins for underwater warfare, he thinks their intelligence has been overestimated and their potential is limited. If dolphins were really intelligent would they not take every opportunity "to pull a human swimmer in difficulties down to death" considering that man has been a ruthless destroyer of dolphins for centuries?

Dr Harrison Matthews' book is quite different in style from two recent books on sea mammals reviewed in *Nature* (270, 641, 1977). It deals only with cetaceans and in greater detail. I would rate it as reading for any biologist or well-informed laymen. □

Summary of rheological activity

Mechanics of Non-Newtonian Fluids. By W. R. Schowalter. Pp. 300. (Pergamon: Oxford, 1978.) £17.50.

THIS text, directed toward graduate students and others beginning research in rheology, begins with a fine motivational chapter 1 and then launches into a five-chapter development of mathematical and physical foundations in terms of tensor analysis. This segment, rigorous but rather dry for students, would require elaboration by an instructor to be fully successful.

The following three chapters are designed to describe rheometric and related flows; Noll's simple-fluid concept is used throughout. Chapter 7 introduces the idea of viscometric flows and provides several illustrations. The equations of continuity and motion for incompressible fluids, in the three major coordinate systems, are

appended. Measurements of the viscometric functions are described in chapter 8, in which numerous flows are studied: plane and cylindrical Couette flow, axial motion in open and annular tubes, jet methods (jet swell, thrust on tube), and the Jackson-Kaye elevated cone procedure. A survey of experimental difficulties is given separately, including end effects, viscous heating, and hole error. Chapter 9 emphasises stretch-history concepts, specialising to extensional flow and perturbations from viscometric flows.

Model-building is encountered in chapters 10 and 11. Elementary models—purely viscous, generalised Newtonian, and linear viscoelastic (differential and integral) fluids—are found in chapter 10. For the first time molecular concepts are introduced, through the dilute-solution polymer dynamics theory of Zimm. The latter treatment is

somewhat patchy and needs to be read with the five chapter appendices to be coherent. The appendices describe Gaussian springs, Brownian motion, hydrodynamic interaction, stress tensor construction, and finally full solution of the eigenvalue problem. (It is unfortunate, however, that the relaxation time τ_r is implied on p155 to represent the response of the p/h sub-molecule rather than the p/h normal mode.) Chapter 11 generalises this material in various ways, including a description of the Oldroyd approach and the use of non-linear time derivatives in modelling. Commentary on many of the models is so brief that a trek to the cited literature is really required.

Chapter 12 on applications comes close to several engineering problems. Again, the treatment is a survey, but this reader found it quite successful: boundary layer theory, converging flow, falling sphere, extensional motion, flow in packed beds, transients, secondary motion, stability theory, extruder analysis, orthogonal rheometer and

inclined open channel. Chapter 13 concludes the book with another excursion into the microscopic, 'Suspension Rheology'. Both rigid and deforming particles are considered, with most detail given to dilute emulsions.

Arising from notes used by Professor Schowalter in over ten years of teaching, the book contains homework problems appended to 11 of the 13 chapters and ample references. Few data are given—only three figures show data points, although there are many schematic drawings—and notation is cumbersome in places. However, the writing style is clear and contains a fine flavour of good humour, and relatively few misprints have crept in. One is advised to ignore the purple and lavender cover and use this text as a guide to the wide variety of rheological activity during the modern transition of 1950–75.

Michael C. Williams

Michael C. Williams is Professor in the Department of Chemical Engineering at the University of California, Berkeley.

Atomic absorption spectroscopy

Atomic Absorption, Fluorescence and Flame Emission Spectroscopy: A Practical Approach. By K. C. Thompson and R. J. Reynolds. Pp. 319. (Charles Griffin: London and High Wycombe, UK, 1978.) £15.

THE second edition of this book, first published in 1970, includes coverage, in varying detail, of the very extensive advances which have been made in atomic spectroscopy in the intervening years. In some areas, however, the extent of the coverage leaves something to be desired. There is commendable emphasis on safety, of which the reader should take careful note: unfortunately, burner explosions are not unknown.

The book can be considered in two main sections, one being principally chemical and the other instrumental. The chemical section covers very thoroughly the areas of applications, chemical techniques and interferences in atomic absorption spectroscopy (AAS), although some of the instrumental procedures described tend to be somewhat dated. For instance, the inexperienced reader would be forgiven for thinking that digital readout is a rare feature, whereas, in fact, it is incorporated in nearly all present-day instruments. It is also noticeable that strong emphasis is given to the relatively little used hydride technique,

whereas the very important area of flameless electrothermal AAS is relegated to the chapter on "Some further techniques"; and it should be mentioned that some authorities claim considerably lower detection limits for

Molecular models

Molecular and Crystal Structure Models. By A. Walton. Pp. 201. (Ellis Horwood: Chichester, UK, 1978.) £9.

MAKING models of the physical world is the stuff of science. Extending and refining these models is what we are doing when we do research. Nowhere is the concept of models more evident than in chemistry. Both at the detailed level of molecular orbitals and, more commonly, in the consideration of three dimensional structure we consider molecules to be representable by models which we can imagine actually constructing as tangible objects.

Dr Walton's book surveys most of the commercially available molecular models and contains advice on do-it-yourself versions. The survey is not exhaustive (an exhaustive survey would soon date), but it is sufficiently wide to be a useful first step for anyone looking for a particular feature.

Models showing special features or behaving in special ways are commonly constructed in research and this book will provide useful tips for that would-be modeller. It is, however, to

some elements than those given in the table on pages 33 and 34.

On the instrumental side, it seems that the authors have a bias against double-beam instruments and the reader is advised to be cautious in accepting the advice given. It is also felt that the guidance on performance parameters could be clearer for the inexperienced user. Again, it is noticeable that only brief mention is made of microprocessor-based instruments, although these now represent a high proportion of those available.

Flame emission and atomic fluorescence spectroscopy are covered in a separate chapter, primarily from the point of view of comparison with AAS. In this respect, an unfortunate weakness is the fact that the very important and competitive (with AAS) technique of plasma emission is dismissed in five lines.

A very extensive bibliography is given at the end of each chapter, but it might have been appropriate to mention that a complete atomic absorption bibliography is available. Overall, the book can be recommended to both new and more experienced users of AAS from the chemical standpoint but with reservations on the instrumental side.

M. A. Ford

M. A. Ford is Technical Director of Perkin-Elmer Limited, Beaconsfield, UK.

the teacher that it will most appeal, providing as it does descriptions of most of the off-the-shelf models, and photographs of many. In it one should be able to find the (non-ideal) model which is a good compromise and which can be provided within the departmental budget for a class of students.

Apart from being inexhaustive, the book suffers from, inevitably, describing each model in a different way. It is particularly unfortunate that it was not possible to have photographs of every model type. This makes it difficult to use for searching out models of a particular type, but it does make it readable. The principal deficiency is, however, the lack of information on consumer-response—is it easy for students to see the point the lecturer is making? Do the students like building these models and do they understand the principles that they are supposed to demonstrate? What are their deficiencies? Perhaps the only answer, as every teacher wishes to emphasise different aspects, is to use this book (with its extensive cross-referencing) to narrow down the choice and then try the models oneself.

S. D. Dover

S. D. Dover is Lecturer in Biophysics at King's College, University of London, UK.

Sedimentary environments

Ancient Sedimentary Environments. Second edition. By R. C. Selley. Pp. 287 (Chapman and Hall: London, 1978). Hardback £8; paperback £4.95.

THIS is an inexpensive book, in which the essential features of the major sedimentary environments are succinctly described. In a book of 287 pages, the treatment does not attempt to be detailed and each synthesis is supported by a generally well chosen list of references. The references, which form 17% of the text, are one of the strengths of the book, for they provide either the student or the experienced geologist with basic references up to 1977. Chapters cover, sedimentary environments and facies; river deposits; wind-blown sediments; lake deposits; deltas, linear clastic shorelines; mixed clastic; carbonate shorelines; shelf deposits; carbonate and terrigenous; reefs; flysch and turbidites; pelagic deposits, and sedimentary models, mythical and mathematical. As might be expected, the emphasis reflects the author's wide field experience, but the omission of glacial sediments is surprising.

The opening chapter contains definitions and discussions of a sedimentary environment and facies. Although brief, the discussion is a clear statement of important basic concepts. For instance—"One of the main problems of determining the origin of ancient sediments is that, though essentially reflecting depositional environments, they also inherit features of earlier erosional and non-erosional phases"—a truism which gives rise to many problems in interpretation.

The author points out that it is only sedimentary structures (and palaeocurrents) which unequivocally indicate the depositional environment. The five defining parameters of a sedimentary facies—geometry, lithology, sedimentary structures, palaeocurrents and fossils—are examined in an instructive way, flavoured with many cautions derived from experience.

In many cases, environmental interpretation must be based on borehole or seismic data, so the inclusion is very appropriate of a general section on the use of vertical grain-size profiles from geophysical logs and the use of the down-hole dipmeter.

The whole text is intended as a practical guide to "environmental interpretation [which] is at best an imprecise art, rather than a deterministic scientific discipline", though the author's treatment is a good preparation for

travelling along the latter route. Generally, each chapter has a main section covering one or more case histories, followed by sections giving wider views of the particular sedimentary facies, its economic significance, subsurface recognition and finally a list of references. Numerous clearly presented diagrams reduce the need for lengthy descriptions.

By its very nature, the book is a compilation of generalisations, but these are made by a perceptive geologist who continuously reminds his readers that the exceptions are the

really interesting problems. The whole presentation is admirably clear and concise, making it a most suitable book for a second-year university course. Geologists at all levels will gain much information from the eminently readable and witty style, but the most important impact is the encouragement of a discriminating and critical sifting of geological evidence. At such an economical price, the book is a good investment.

D. Hamilton

D. Hamilton is Senior Lecturer in Geology at the University of Bristol, UK.

Physiology of fungal colonies

Practical Fungal Physiology. By P. M. Robinson. Pp. 122. (Wiley: Chichester, UK, and New York, 1978.) £3.50.

ONE can only agree with the author's opening statement in the preface to this book that "The potential of fungi as experimental material is not always fully exploited". This book provides a series of experiments designed to introduce a student to some basic aspects of fungal physiology. There are nine chapters and the suggested experiments are described in each chapter within an overall account of the cellular processes involved. Topics dealt with include spore germination, hyphal growth, fungal nutrition, morphogenetic substances, staling, colony morphology, mycostasis and continuous culture. The experiments described in most chapters are very basic and have been designed to utilise a minimum of expensive equipment. There are references to original papers in the relevant areas and figures are included to

illustrate the expected results of certain experiments. Experiments are described in flowsheet form and adequate details are provided for media recipes, inoculation times and general experimental protocols.

Overall, this simplified approach should provide a reasonable introduction to the physiology of the fungal colony. It is, perhaps, unfortunate that many of the experiments involve aspects of fungal physiology of whose cellular and biochemical mechanisms we have little understanding. This limitation is compounded by the omission of experiments involving well understood phenomena such as the phototropic responses of *Phycomyces*.

Despite these criticisms the book should prove useful to school and university teachers looking for ideas to be included in an introductory course on mycology. Also, if the book helps move the teaching of mycology away from the classical taxonomic approach, then it is to be welcomed.

Keith Gull

Keith Gull is Lecturer in Microbiology at the University of Kent, Canterbury, UK.

Molecular dynamics

Molecular Structure and Dynamics. By W. H. Flygare. Pp. 696. (Prentice-Hall: Englewood Cliffs, New Jersey, and Hemel Hempstead, UK, 1978.) £18.25.

ONE can tell from the front leaf of the dustcover that this is a crowded treatise. There is the ^{13}C -NMR spectrum of a methyl group with its free induction decay, the ESR spectrum of the cyclopentyl radical, the Raman spectrum of CO_2 , the low resolution IR spectrum of CH_2Cl_2 , the radial wave function of the 1^{-5s} orbital, a coordinate system for electron scattering from a triatomic molecule and another relating laboratory and molecular axes, and the X-ray structure factor for

metallic potassium. If the back leaf had been used to show the electron density difference plot of HF, the splitting pattern of a ^2D state in an octahedral field (with spin-orbit interaction), the Doppler spectrum of interstellar formaldehyde and the symmetry elements of CH_4 , then one could have dispensed with the statement of contents.

The book would be suitable for a BSc honours course in chemical physics or for a postgraduate course for spectroscopists. It is a well written book and I found little to quarrel with in either the contents or their presentation.

I must, however, admit to a preference for shorter books on a narrower front. Seven hundred pages is indigestible and I cannot envisage ever starting such a book and getting to the end. Of course, there are books on my shelf that I use just for reference, and per-

haps this will be added to their number. Professor Flygare clearly hopes for more—for example, by challenging the reader with problems at the end of each chapter.

The difficulty with an epic work is that one dare not be discursive or one cannot get it all between two hard covers. Let me take, for example, the section on scattering in this book. The fifty pages devoted to this topic is sufficient to include topics such as vibrational and rotational inelastic scattering or the relationship between the potential energy surface for a reaction and the energy distribution in the products.

Mitochondrial and plastid heredity

Organelle Heredity. By N. W. Gillham. Pp. 602. (Raven. New York, 1978.) \$64.35.

NON-MENDELIAN HEREDITY has been the Cinderella of genetics ever since Correns discovered it exactly 70 years ago. It has long been complicated, confused and experimentally intractable. It is still complicated, but powerful new techniques, ably described in this new book by one of their chief wielders, are rapidly reducing the confusion.

For over a decade it has been clear that there are two fundamentally different causes of non-Mendelian heredity. One of these, the direct inheritance of preformed cell structure—seemingly independently of DNA—is well established only for the ciliate cortex. The more widespread cause is the existence of DNA inherited other than in a Mendelian fashion. Sometimes such DNA is nuclear—B-chromosomes are the most obvious example—but more usually it is cytoplasmic. Although there are numerous scattered cases where cytoplasmic DNA constituting the genome of intracellular viruses or cellular endosymbionts causes non-Mendelian inheritance, cytoplasmic DNA occurs regularly only in plastids and mitochondria; the genetics of these, not of organelles in general, is the subject of Gillham's excellent book.

The book is the most thorough treatment yet of mitochondrial and plastid genetics, and deserves to be read widely by geneticists, biochemists, cell biologists and advanced students. Although it excludes evolutionary discussions, it will be invaluable to all interested in organelle evolution. Fifteen of the twenty-one chapters concentrate on transmission genetics, the four on baker's yeast and the four on *Chlamydomonas* forming the heart of the book.

There is no mention of the Born approximation or of semi-classical quantisation (apart from the Bohr atom). The book would not be sufficient in itself for a postgraduate course on molecular dynamics and would be a little thin even for an advanced undergraduate course on this topic.

Perhaps I am being petty. It is in the main a fine work which I shall find very useful. I doubt, however, that it will be adopted as a course book in many British universities. J. N. Murrell

J. N. Murrell is Professor of Chemistry at the University of Sussex, Brighton, UK.

Nuclear transmission genetics was substantially worked out within a single decade of Morgan's first concentration on *Drosophila*. Yet, although Ephrussi and Sager made yeast and *Chlamydomonas* the *drosophilas* of cytoplasmic heredity decades ago, we still do not understand it. This is because until the past decade the characteristic uniparental inheritance of organelle genes, and the scarcity of different mutants, precluded traditional genetic analysis of segregation and recombination. Much of the recent progress stems from strictly genetic advances—the ability to obtain biparental inheritance and to induce and isolate a greater variety of mutants. This has led to an impressive array, often bewildering to the outsider, of new mapping techniques; and it is valuable to have them so clearly laid out in one place.

The discovery of organelle DNA has also been important, especially on the psychological side as a booster of the intellectual respectability of the field. Wherever possible Gillham integrates the molecular and genetic approaches, but where this cannot be done, as in the conflicting data on the inheritance of *Chlamydomonas* chloroplast DNA, he simply describes the basic data. His account of the conflicts between Sager's work and his own are admirably balanced. Particularly valuable are the comparisons between the yeast and *Chlamydomonas* work. Although yeast is simpler and more intensively studied, in the long run *Chlamydomonas* will be ideal for studying the interactions between biparentally inherited nuclear DNA, 'maternally' inherited plastid DNA and its 'paternally' inherited mitochondrial DNA. ('Maternal' and 'paternal' are peculiarly inappropriate for *Chlamydomonas* which is isogamous and has an organelle like the acrosomal tubule of sperm on its so-called 'maternal' gametes.)

Mitotic segregation prevents enumeration by the *cis-trans* test of the polypeptides coded by organelle DNA,

but genetic techniques can help in assigning specific gene products to nuclear or organelle DNA. Gillham ably describes the combined genetic and biochemical study of mutants, the use of interspecific hybridisation and the analysis of mammalian cell hybrids in tissue culture. DNA hybridisation studies of mules and hinnies have shown mitochondrial DNA to be maternally inherited, as in fungi. Here, however, the mechanism may simply be dilution of sperm mitochondria by the vast excess of female ones in the egg. In fungi, many of which are isogamous like *Chlamydomonas*, this cannot be so; curiously, twelve years after I discovered chloroplast fusion in *Chlamydomonas* the cytological fate of mitochondria in fungal zygotes is still unknown, although in 1978 Gaffal demonstrated mitochondrial fusion in zygotes of the alga *Polytoma*. As Gillham points out, cytology is lagging behind genetics and biochemistry.

Although emphasising genetics, Gillham also summarises present biochemical, cytological and physiological knowledge of the structure and functions of organelle DNA. The first chapter is an up-to-date outline of the structure and function of plastids and mitochondria. It is followed by one on the structure and replication of mitochondrial and chloroplast DNA, including brief accounts of the underlying techniques. The two chapters on the RNA- and protein-synthetic machinery of plastids and mitochondria, and their biogenesis, describe the evidence that organelle RNA is coded by organelle DNA; the majority of proteins, on the other hand, including nearly all the ribosomal ones, are coded in the nucleus and synthesised outside the organelles.

The remaining two chapters discuss the biosynthesis of the mitochondrial inner membrane and the thylakoids. Here also most of the proteins are coded by the nuclear DNA; only a handful are yet known to be coded by the organellar plasmids. I suspect that the bulk of this DNA—like nuclear DNA—does not code for proteins. The pace of advance of both the genetic and the biochemical methods Gillham so clearly describes is such that we shall soon know; things too recent to be included are constantly being discovered, like the presence of split genes in both mitochondria and plastids.

This well produced book, with its ample references, is a milestone in the history of genetics.

announcements

Awards

The following have been elected Fellows of the Royal Society:

Professor John Robert Laurence Allen, Professor of Geology in the University of Reading; **Professor Michael Farries Ashby**, Professor of Engineering Materials in the University of Cambridge; **Professor Evelyn Martin Lansdowne Beale**, Technical Director of Scicon Computer Services Limited; **Professor John Maxwell Cowley**, Professor of Physics at Arizona State University; **Professor Bernard Crossland**, Professor, and Head of the Department, of Mechanical and Industrial Engineering in the Queen's University, Belfast; **Professor Durward William John Cruickshank**, Professor of Chemistry in the University of Manchester Institute of Science and Technology; **Dr Michael Joseph Crumpton**, Head of the Division of Biochemistry at the National Institute for Medical Research, London; **Professor John Hilton Edwards**, Professor, and Head of the Department, of Clinical Genetics and Professor of Human Genetics in the University of Birmingham; **Dr Michael Elliott**, Senior Principal Scientific Officer at Rothamsted Experimental Station; **Professor Michael Anthony Epstein**, Professor, and Head of the Department, of Pathology in the University of Bristol; **Professor William Charles Evans**, Professor, and Head of the Department, of Biochemistry and Soil Science in the University College of North Wales, Bangor; **Dr Raymond Freeman**, University Lecturer in Physical Chemistry in the University of Oxford; **Professor Richard Lavenham Gardner**, Henry Dale Research Professor of the Royal Society at the University of Oxford; **Professor Alastair Graham**, Emeritus Professor of Zoology in the University of Reading; **Dr Cyril Hilsum**, Chief Scientific Officer in the Physics Group at the Royal Signals and Radar Establishment, Malvern; **Professor David Alan Hopwood**, John Innes Professor of Genetics in the University of East Anglia and Head of the Genetics Department of the John Innes Institute; **Dr Keith Usherwood Ingold**, Associate Director of the Division of Chemistry in the National Research Council of Canada, Ottawa; **Dr Edward Irving**, Geophysicist in the Department of Energy, Mines and Resources, Ottawa, Canada; **Professor Geoffrey**

Melville Jones, Professor of Physiology and Director of the Defence Research Board Aviation Medical Research Unit, McGill University, Montreal, Canada; **Professor Devendra Lal**, Director of the Physical Research Laboratory, Ahmedabad, India; **Professor Michael Franz Lappert**, Professor of Chemistry in the University of Sussex; **Professor Ian Grant Macdonald**, Professor of Mathematics at Queen Mary College in the University of London; **Dr Digby Johns McLaren**, Director-General of the Geological Survey of Canada, Ottawa; **Professor Robert McCredie May**, Professor of Jersey; **Patrick Anthony Merton**, Reader in Human Physiology in the University of Cambridge; **Professor Brenda Milner**, Professor of Psychology at the Montreal Neurological Institute, Canada; **Professor Kenneth Murray**, Professor of Molecular Biology in the University of Edinburgh; **Dr Denis Noble**, Lecturer in Physiology in the University of Oxford; **Professor Martin John Rees**, Plumian Professor of Astronomy and Experimental Philosophy in the University of Cambridge; **Professor Paul Henry Roberts**, Professor of Applied Mathematics in the University of Newcastle upon Tyne; **Professor Milton Robert James Salton**, Professor of Microbiology at New York University; **Professor Harry Smith**, Professor, and Head of the Department, of Microbiology in the University of Birmingham; **Dr Godfrey Harry Stafford**, CBE, Director of the Rutherford Laboratory, Chilton, Didcot; **Professor John Griggs Thompson**, Rouse Ball Professor of Mathematics in the University of Cambridge; **Professor David James Thouless**, Professor in the Department of Engineering and Applied Science, Yale University, Connecticut; **Dr Winifred Anne Tutin**, Principal Scientific Officer of the Freshwater Biological Association, Ambleside, and Honorary Reader in Botany in the University of Leicester; **Dame Janet Maria Vaughan**, DBE, formerly Principal of Somerville College, Oxford; **Professor David Alan Walker**, Professor, and Head of the Department, of Biology in the University of Sheffield; **Professor Janet Vida Watson**, Professor of Geology at the Imperial College of Science and Technology in the University of London; **Professor Olgierd Cecil Zienkiewicz**, Professor, and Head of the Department, of Civil Engineering in the University College of Swansea, Wales.

The Council of The Institute of Physics has made the following awards for 1979: Bragg Medal and Prize to **Sister Maureen Hurst** of La Retraite High School, London; Charles Chree Medal and Prize to **Professor J. T. Houghton** of the University of Oxford; Charles Vernon Boys Prize to **Dr D. C. Robinson** of the Culham Laboratory; Duddel Medal and Prize to **Dr J. R. Sandercock** of the Laboratories RCA, Ltd, Zurich; Glazebrook Medal and Prize to **Dr T. G. Pickavance**, formerly of the Rutherford Laboratory; Guthrie Medal and Prize to **Professor D. H. Perkins** of the University of Oxford; Maxwell Medal and Prize to **Dr. C. H. Llewellyn Smith** of the University of Oxford; Thomas Young Medal and Prize to **Professor C. Cohen-Tannoudji** of the Collège de France, Paris.

The Clough Medal for 1978-79 has been awarded to **Professor M. H. P. Bott**, Department of Geological Sciences, University of Durham, in recognition of distinguished contributions towards the elucidation of geological structures by geophysical means in and around Scotland and the North of England.

The Clough Award for 1978-79 has been conferred on **Dr D. J. Fettes** of the Institute of Geological Sciences, Edinburgh, in appreciation of his work on the metamorphism of the Dalradian rocks of Scotland.

The William Hopkins Prize of the Cambridge Philosophical Society has been awarded to **Dr D. P. McKenzie**, of King's College, for his work on the theoretical geophysics of the solid earth, with particular reference to plate tectonics.

The Society for the History of Alchemy and Chemistry, has awarded the 1978 Partington Prize to **Dr Reinhard Löw** of the Institut für Philosophie der Universität München.

The Kurt P. Richter Prize has been established for meritorious research in the area of psychoneuroendocrinology. This essay prize, the sum of \$1,000 will be awarded annually for the best manuscript or essay submitted by a scientist or physician under 35 years of age. Write to: Dr Fleur L. Strand, Secretary, International Society of Psychoneuroendocrinology, New York University, Washington Square, New York, New York 10003.

The Trustees of the Lady Tata Memorial Trust invite applications for Awards (both predoctoral and postdoctoral) for research on leukaemia, in the Academic Year beginning October 1979. Write to the Secretary of the (European) Scientific Advisory Committee, Lady Tata Memorial Trust, Chester Beatty Research Institute, Fulham Road, London SW3, UK.

The Douglas Bomford Trust announces the offer of a Travelling Scholarship in Agricultural Engineering to be awarded in the year 1979-80. Write to The Institution of Agricultural Engineers, West End Road, Silsoe, Bedford, UK.

One or two Unilever European Fellowships will be awarded for the academic year 1979-80, for either (a) research in biochemistry in a laboratory in continental Europe by British citizens resident in Great Britain or (b) work in Britain by European nationals. Applicants should hold a PhD degree or offer evidence of having equivalent qualifications or experience. The Fellowships will normally be within the UK University Lecturer scale. Write to the Executive Secretary, The Biochemical Society, 7 Warwick Court, London WC1, UK.

The 1979 Nikon's Small World Photomicro/macrography Contest is open to everyone interested in scientific and industrial photography. The subject matter is unrestricted; any type of specimen is acceptable. Any photomicro/macrography technique may be used, including phase contrast, polarised light, fluorescence, dark field, interference, and reflected light. This year's deadline will be 2 July 1979, and the first-prize award is a \$1,500 vacation trip or \$1,500 worth of Nikon instruments or photographic equipment. For a copy of the official contest rules and entry form, write to Ms Susie Weiss, Nikon's Small World Competition, Nikon Incorporated, Instrument Division, 623 Stewart Avenue, Garden City, New York 11530.

The Roussel Prize is given every two years to a chemist or a biochemist whose work has been chosen as the most outstanding by an international committee of distinguished scientists in the field. The next Prize (\$20,000) is scheduled for April 1980, and will be concerned with outstanding work on Chemistry or Biochemistry of Steroids and other Squalenoids published before 30 September 1979. Candidates may be of any nationality and from any laboratory. They should be introduced by a person of high scientific standing and supported by two other referees. Write to Professor J. Mathieu, Centre de Recherches, Roussel Uclaf, 93230 Romainville, France.

Meetings

2-6 April, **Appropriate Energy Technology for Development**, Glasgow (Dr J. Twidell, Dept of Applied Physics, University of Strathclyde, Glasgow, UK).

17 April, **Pain—New Trends in Research and Management**, New York (Eugene and Estelle Kone, American Pain Society, 280 Knollwood Drive, New Haven, Connecticut 06515).

19 April, **Gas Injection into Liquid Metals**, Newcastle upon Tyne (Dr A. E. Wraith, Dept of Metallurgy and Engineering Materials, The University, Newcastle upon Tyne, UK).

23-27 April, **Remote Sensing of the Environment**, Ann Arbor (The University of Michigan Extension Service, Dept of Conferences and Institutes, 412 Maynard St, Ann Arbor, Michigan 48109).

8-11 May, **International Symposium on Personal Protective Equipment**, Torremolinos (Servicio Social de Higiene Y Seguridad del Trabajo, Instituto Territorial, Apartado de Correos 615, Sevilla, Spain).

15 May, **Mechanisms of Ion Selectivity**, Aberdeen (17 May, Cambridge) (Faraday Division, The Chemical Society, Burlington House, London W1, UK).

22 May, **Transport across Interfaces**, Bristol (Faraday Division, The Chemical Society, Burlington House, London W1, UK).

18-19 June, **Virus-Lymphocyte Interactions: Implications for Disease**, Cleveland (Max R. Proffitt, Dept of Immunology, Cleveland Clinic Foundation, Cleveland, Ohio 44106).

2-3 July, **Laboratory Safety in Higher Education**, Manchester (Mrs S. Leclercq, The Chemical Society, Burlington House, Piccadilly, London W1, UK).

2-6 July, **Management Studies for Production Chemists**, Slough (Mrs S. Leclercq, The Chemical Society, Burlington House, Piccadilly, London W1, UK).

4-6 & 10-13 July, **4th National Oceanographic Symposium**, Johannesburg & Cape Town (Symposium Secretariat S.189, CSIR Conference Division, PO Box 395, Pretoria 0001, South Africa).

6-18 July, **Automation in Industrial and Clinical Chemistry**, London (Scientific Symposia Ltd, UTP House, 33-35 Bowling Green Lane, London EC1, UK).

9-13 July, **Automatic Methods of Analysis**, Swansea (Mrs S. Leclercq, The Chemical Society, Burlington House, Piccadilly, London W1, UK).

10 July, **Remote Measurement of Sea-State and Oceanic Winds**, Birmingham (Royal Meteorological Society, James Glashier House, Grenville Place, Bracknell, Berkshire, UK).

17 July-19 August, **Techniques of Molecular Biology**, Santiago (Dr Jorge E. Allende, Casilla 6671, Santiago 7, Chile).

15-22 July, **Workshop on Bioethics and Public Policy**, New York (Institute of Society, Ethics and the Life Sciences, 360 Broadway, Hastings-on-Hudson, New York 10706).

19-20 July, **Heat Treatment—Methods and Media**, Birmingham (The Meetings Secretary, The Institute of Metallurgical Technicians, Northway House, Whetstone, London N20, UK).

23-25 July, **Isotopes: Essential Chemistry and Applications**, Surrey (Mrs S. Leclercq, The Chemical Society, Burlington House Piccadilly, London W1, UK).

13-24 August, **The Scientific and Mathematical Foundations of Engineering Acoustics**, Massachusetts (Office of the Summer Session, Room E19-356, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139).

15-17 August, **20th Canadian High Polymer Forum**, Quebec (Dr Ian McEwan, CIL Paint Research Laboratory, 1330 Caslefield Ave, Toronto, Ontario, Canada M6B 4B3).

newly on the market

Atomic absorption system. Pye Unicam. With microprocessor data handling and a completely new video furnace programmer, Pye Unicam's atomic absorption system SP9 is flexible yet extremely easy to use. Available for both flame and flameless operation, the system SP9 incorporates many extra features such as silica-coated optics.

Circle No. 42 on Reader Enquiry Card.

The Pye Unicam furnace autosampler

Tunable laser source. Glen Creston introduce the EDSI, which is a compact, bench top tunable laser source which covers the range 400–700 nm. It is easy to operate, air cooled and plugs into any 13 A socket. The output from the dye is 30 μ J at 25 hZ, peak power 10 kW or greater and spectral line width approximately 1 nm. The unit is suitable for a wide variety of spectroscopic applications and, in view of its relatively low cost, it is also ideal for teaching purposes.

Circle No. 43 on Reader Enquiry Card.

Tube gel chamber. Miles. A newly redesigned tube gel chamber for electrophoresis has been introduced by Miles Laboratories. Versatile and compact, the Canalso tube gel chamber is suitable for electrophoresis in uniform or gradient gels, isoelectric focusing, and isotachopheresis.

Circle No. 44 on Reader Enquiry Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the cover.

Portable printing calculator. Decimo. The Vatman mini video from Decimo is a portable 10-digit fast print and display model which is fully rechargeable and supplied complete with adaptor. Features include: fully independent 4 key memory; sigma for auto entry to memory; percentage key; facility for working on display only and whilst in this mode feature for printing figure shown on display. Dimensions 220 $\times$ 105 $\times$ 55 mm.

Circle No. 45 on Reader Enquiry Card.

Wound probe system. Radiation Monitoring Devices. A small, highly sensitive probe system for detecting radiation in wounds caused by nuclear accidents has been introduced by Radiation Monitoring Devices. The RMD wound probe system WPS-1 uses a high efficiency cadmium telluride probe, which requires no photomultipliers, high voltage, or liquid nitrogen cooling, to detect γ radiation in wounds. Sensitive to energies as low as the 17 keV of plutonium, the standard wound probe incorporates a 3.5 mm diameter cadmium telluride crystal. In the field it can be battery powered and used with a miniature counter.

Circle No. 46 on Reader Enquiry Card.

Haemoglobin A₁ test kit. Bio-Rad Laboratories has developed a convenient and precise haemoglobin A₁ by column test that requires minimal preparation and only one column elution. The test measures the amount of glycosylated haemoglobin (HbA₁) in whole blood. Blood (100 μ l) is mixed with an efficient lysing agent. An aliquot of the haemolysate is then applied to a cation exchange resin in a disposable column. The percentage of HbA₁ is easily determined spectrophotometrically. The test kit comes complete with reagents and columns sufficient for 100 assays.

Circle No. 47 on Reader Enquiry Card.

Liquid scintillation system. Packard. The tri-carb 2660 is a liquid scintillation system which is computer controlled. Fifteen measurement programs are stored on a flexible diskette for random access. The system requires no user interaction other than loading samples. Programs can be user defined. Sample activity is computed from efficiency correlation parameters automatically established by the system. The servo-tray sample changer is multi-user orientated.

Circle No. 48 on Reader Enquiry Card.

Multi-detector γ counter. LKB-Wallac. A high throughput multi-detector λ counter has been introduced by LKB-Wallac to supplement their range of λ counters for use in biochemistry and clinical chemistry. The 1260 Multi-Gamma has 12 detectors and a built-in microcomputer, which because of its rapid spline function program, allows users to produce radioimmunoassay concentration results even more rapidly than other multi-detector instruments which do not use microcomputers. Using the 'rapid load' sample tray a set of 120 RIA samples can be counted, the standard curve plotted, and concentrations, with error limits, can be calculated in 16 minutes.

Circle No. 49 on Reader Enquiry Card.

Electron microscope. The Zeiss EM 109 has a 3.44Å resolution, a high degree of specimen protection from excessive irradiation and the elimination of contamination. The improvements in this electron microscope include a camera system that is totally outside the vacuum, an automatic focusing system for maximum specimen protection, and a vacuum system providing ultra-clean specimen conditions. Also with the new Micro-Dose Focusing system, the specimen area to be studied can be selected at low intensity. A push of a button shifts the image to a non-critical area adjacent to the selected detail, automatically switches to high magnification, making precise focusing easy for the operator and protecting the critical specimen area from unnecessary exposure to the electron beam. After selection of the desired magnification, the electron beam switches automatically back to the area to be studied without losing focus.

Circle No. 50 on Reader Enquiry Card.

The Zeiss EM 109

Richest field adapter. Celestron International announces a new product called a Richest Field Adapter. This device is used on Celestron's existing line of telescopes to quadruple the brightness of faint deep sky objects and also double the actual field-of-view through the C5, C8 or C14 telescopes. The new 20-mm Erfle Ocular is also introduced which gives a wide apparent field of approximately 75°. Works extremely well on all Celestron telescopes.

Circle No. 51 on Reader Enquiry Card.

Ion beam processing unit. Ion Tech have introduced a new surface preparation version of the very successful Super Microlap. This new ion beam thinning unit possesses all the features of the advanced Super Microlap which will thin copper specimens at 50 µm per hour. In addition this new model B305W has a servo motor drive and control system for rocking a wide beam saddle-field ion source over a rotating scanning electron microscope specimen. The B305W can be supplied either as a module for retro-fitting to an existing pumping system or can be supplied installed as an integral package with the Ion Tech B500 high vacuum pumping system.

Circle No. 52 on Reader Enquiry Card.

The Ion Tech B305W

Filter units. Millipore. Millex-GS single-use filter units, from Millipore, provide the pharmacist and technician with the ideal means of sterilisation and clarification of small-volume ophthalmic solutions. Containing a 0.22 µm, low-extractable, cellulose-ester membrane filter, Millex-GS removes particulates, fibres and microorganisms from extemporaneously prepared solutions and in conjunction with a sterile syringe, needle and bottle, comprises the complete system for aseptic dispensing of volumes up to 250 ml.

Circle No. 53 on Reader Enquiry Card.

Photoresist illuminators. Oriel Scientific announces a new range of high performance photoresist illuminators providing collimated UV light with a beam uniformity of better than $\pm 5\%$. Applications include processing thin and thick films, printed circuit boards, optical encoders, LCD displays, plasma panels, graticule manufacture and UV curing. The illuminators are available in convenient arrangements giving horizontal or vertical beams for contact, proximity or projection printing.

Circle No. 54 on Reader Enquiry Card.

Rotary table for photoresist illuminators. Oriel. The Oriel model 8422 rotary table with dual alignment fixtures allows exposure of one mask while the operator unloads and loads the previously exposed substrate. This system can be used for contact or proximity printing and will accept various size masks and substrates. Accurate alignment is made easy with micrometer settings for X Y Z on θ . Two micrometers can also be positioned in various locations along the X axes to accommodate various size substrates.

Circle No. 55 on Reader Enquiry Card.

Liquid chromatograph. Schoeffel. A new, full-featured high performance liquid chromatograph—the Series 750—has been introduced by the Schoeffel Instrument Division of Kratos. The new system is suitable for high pressure analytical separations and medium flow semi-preparative separations. Because the system is modular, the chromatographer may initially acquire a basic system and later add to that system. The system features a dual piston, high pressure pump, a high pressure gradient programmer, a column oven, and a multi-wavelength UV detector. The components may be used independently or together as a complete system.

Circle No. 56 on Reader Enquiry Card.

Pyrogen test kit. Microbiological Associates. The Limulus amoebocyte lysate test is a means of rapidly detecting the presence (or absence) of endotoxins and radiopharmaceuticals. A clear result is achieved in an hour or less. In addition, the LAL test has more than ten times the sensitivity of the rabbit test. Now Microbiological Associates is able to offer from stock the only licensed kit, to allow the user to eliminate any risk of cross contamination and to provide a full set of controls. Lysate is predispensed in pyrogen-free vials and the user need only add 0.2 ml of sample, using one of the pyrogen-free pipettes supplied (one for each test), and place in a heating block for up to an hour. The controls are included.

Circle No. 57 on Reader Enquiry Card.

Automatic powder diffractometer. Philips. A new version of the Philips APD 10 automatic powder diffractometer has now been introduced. This up-dated unit retains the essential features of the former model, but with a revised layout to optimise system modularity and permit more convenient operation. With mini-computer control and a wide range of software options, the APD 10 enables routine analyses to be carried out far more rapidly than is possible with manual diffractometers. Precision is also ensured by the incorporation of automatic calibration corrections.

Circle No. 58 on Reader Enquiry Card.

The new Philips APD 10

Liquid chromatograph. Shandon Southern. A high performance liquid chromatograph, has been developed at the University of Edinburgh in collaboration with Shandon Southern. Within minutes it can separate minute quantities of the different chemical components of complex chemical mixtures. The chromatograph works by pumping a small sample of the mixture of interest under high pressure (up to 5,000 lb per square inch) through a 5-mm bore stainless steel tube. The tube contains a special absorbent through which the different components of the mixture migrate at different speeds. Thus a 'time-profile' is produced on the instrument's read-out system as the sample is expelled from the column, revealing the presence and measuring the quantities of the various components in the original mixture.

Circle No. 59 on Reader Enquiry Card.

Industrial fluidised baths. Techne. A new series of industrial fluidised baths providing a working depth of up to 48 inches and a working diameter of up to 24 inches is available from Techne Inc. Called models IFB-111, -121, -131, and -510, the units use fluidised aluminium oxide (a safe, dry, non-toxic, stable material) as a heat transfer medium up to 600 °C.

APPOINTMENTS VACANT

UNIVERSITE DE LAUSANNE

L'Université de Lausanne ouvre une inscription pour le poste de
**PROFESSEUR ORDINAIRE
DE BIOLOGIE
ANIMALE**

Charges: Direction de l'Institut de biologie animale, enseignement propédeutique en biologie animale (étudiants en sciences et médecine) et enseignement de biologie expérimentale (dans le cadre du certificat).

Recherches: Biologie animale expérimentale, ultrastructure.

Entrée en fonction: 1er septembre 1979. Date-limite de l'inscription: **1er mai 1979**. Les candidatures (curriculum vitae, plan de recherche, publications) doivent parvenir au Doyenat de la Faculté des Sciences, Collège propédeutique 1015 Lausanne (Suisse).

Tout renseignement complémentaire peut y être obtenu.

W30(A)

ST GEORGE'S HOSPITAL MEDICAL SCHOOL (University of London) IMMUNOLOGY POSTDOCTORAL RESEARCH ASSISTANT

required to participate in a three-year C.R.C. research project on the immunological potential of human lymphocytes *in vitro*, with particular reference to chronic lymphocytic leukaemia. Candidates should have a background in membrane or immunochemistry and perhaps cell culture, although training in cell culture could be given. Salary in the range £3,883 to £4,133 to £4,382 (under review) plus £502 per annum London Allowance.

Further particulars and application forms available from the Establishment Officer, St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE. Closing date April 30, 1979. 341(A)

UNIVERSITY OF JUBA SUDAN

Applications are invited for the following posts in the College of Natural Resources and Environmental Studies:

1. PROFESSOR/
ASSOCIATE PROFESSOR/
LECTURER IN FISHERIES;
2. PROFESSOR/
ASSOCIATE PROFESSOR/
LECTURER IN BIOMETRICS;
3. PROFESSOR/
ASSOCIATE PROFESSOR/
LECTURER IN SOIL SCIENCE;
4. PROFESSOR/
ASSOCIATE PROFESSOR/
LECTURER IN LAND USE;
5. PROFESSOR/
ASSOCIATE PROFESSOR/
LECTURER IN WILDLIFE
CONSERVATION AND
MANAGEMENT;
6. PROFESSOR/
ASSOCIATE PROFESSOR/
LECTURER IN ANIMAL
BACTERIOLOGY AND
PATHOLOGY;
7. PROFESSOR/
ASSOCIATE PROFESSOR/
LECTURER IN ANIMAL
GENETICS AND BREEDING.

Salary scales: Professor, £55,460 per annum; Associate Professor, £54,030 to £54,550 per annum; Lecturer, £51,500 to £53,500 per annum (excluding cost of living allowance). (£51=£1.23 sterling.) The British Government may supplement salaries in range £3,894 to £4,542 per annum (sterling) for married appointees or £1,830 to £2,310 per annum (sterling) for single appointees (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages, various allowances; superannuation scheme; annual overseas leave.

Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail to the Personnel Secretary, University of Khartoum, P.O. Box 321, Khartoum, Sudan, by May 8, 1979.

Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. 289(A)

UNIVERSITY OF WARWICK LECTURESHIP IN VIOLOGY

Applications are invited for a new post tenable from October 1, 1979 in the Department of Biological Sciences. Teaching will be within the degree courses taught in the Department, the precise area depending upon the interests and experience of the candidate and requirements of the Department. The successful applicant will be appointed to the Virology Research Group led by Professor D. C. Burke; and will be expected to undertake research which complements one or more of the existing projects. Applications from candidates from all branches of virology will be welcome. Initial salary will be within the first four points of the Lecturer scale: £3,883 by (£4,631) to £7,754 p.a. (under review). Further details and application forms from the Academic Registrar, University of Warwick, Coventry CV4 7AL quoting Ref. No. 35/2A/79. Closing date for receipt of applications May 4, 1979. 366(A)

AUSTRALIA MINISTRY FOR THE ARTS NATIONAL MUSEUM OF VICTORIA

The National Museum of Victoria founded in 1854, is a state government funded museum covering the fields of Zoology, Mineralogy, Paleontology, and Anthropology with a special research interest in Southeastern Australia. The museum is under the control of the National Museum of Victoria Council and staff are employed by the Public Service Board of Victoria. There are eleven curatorial departments with a total scientific staff of 26. Research is supported by one of the largest natural history reference libraries in Australia. The collections contain significant holdings in most animal groups.

Applications are invited from person who possess appropriate qualification for the following position:

CURATOR OF CRUSTACEA

Class "SO-5", Second Division
\$A18,251

The appointee will be responsible to the Director to carry out appropriate taxonomic research, to maintain and curate the departmental collection answer public and professional enquiries and contribute, as required to the educational and exhibition programmes of the museum.

The successful applicant will possess an approved higher degree in Science with a major in Zoology and provide evidence of wide research experience appropriate to the collections, together with ability to maintain collection and advise on museum exhibits.

The successful applicant will, subject to passing a prescribed medical examination, be appointed as permanent officer of the Victorian Public Service. Conditions of service include four weeks' annual leave with holiday pay loading, liberal sick leave, maternity and paternity leave, eligibility for long service leave after completion of ten years' service and a generous contributory superannuation scheme.

Applications in writing, quoting Position No. L08/25/0151/8 and stating qualifications, experience and date of birth, must reach the Secretary, Public Service Board of Victoria, Treasury Place, Melbourne, 3002 Victoria, Australia, by not later than 9.30 a.m. on Wednesday, May 16, 1979.

VICTORIAN PUBLIC SERVICE
W24(A)

UNIVERSITY OF LIVERPOOL DEPARTMENT OF BIOCHEMISTRY TECHNICIAN (ELECTRON MICROSCOPE)

To operate a J.E.M. T7 electron microscope and associated equipment providing a service to several research groups. Candidates should possess H.N.C. or equivalent as a minimum qualification and several years experience, but applications from candidates with lower qualifications will be considered. Salary within a range up to £3,720 p.a. (under review) according to qualifications and experience. Application forms may be obtained from The Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quoting Ref: RV/549/N. 364(A)

DESIGNER (SCIENCE PROJECTS) OPEN UNIVERSITY PRODUCTIONS

Are you interested in the presentation of science through television? There is an opportunity to work on the design and preparation of scientific and technological experiments and demonstrations for Open University television programmes. Applicants must have mechanical workshop skills and should have experience of electronics to HNC level or equivalent. Ability to work in a wide range of scientific areas, e.g. Chemistry, Biology, Geology and Physics is essential.

Based at Alexandra Palace, North London, but it is anticipated that Open University Productions will move to Milton Keynes in 1981.

Salary (under review): £5,890 p.a. (may be higher if qualifications exceptional) by £225 to £7,015 p.a. Relocation expenses considered.

Telephone or write immediately for an application form, enclosing addressed envelope and quoting reference 2183/NA, to **Appointments Department, BBC, London W1A 1AA. Telephone: 01-580 4468, ext. 4619.**

Section Head- Inhalation Toxicity

ICI Central Toxicology Laboratory

This Laboratory provides advisory and experimental services to ICI Limited, for the control of toxic hazards in manufacturing processes and in other fields of growing importance, such as the development of pesticides and food additives. Emphasis is placed on improving and assessing methods for studying the biological effect of foreign compounds and upon understanding mechanisms of toxicity. The provision of toxicological information, prior to product clearance and registration in many countries, is a major activity undertaken by the Laboratory on behalf of the ICI group.

We currently have a vacancy for someone to head our Inhalation Toxicity Section. The job holder will be responsible for managing approximately 18 people who are involved in the provision of a facility to assess any potential health risks through inhalation of chemicals and particulates. The job holder is expected to contribute to the overall management of the Laboratory, and to formulate the correct technical policy for the Section whilst ensuring that results produced are reliable.

The successful candidate will have post-doctoral experience of research on the pulmonary system together with proven ability in managing multi-disciplinary project teams. It is unlikely that any candidate below 30 years of age will have accumulated sufficient experience.

The Laboratory is two miles south of the village of Alderley Edge on the main road (A34) between Manchester and the Potteries on a 300 acre site which the Laboratory shares with ICI's Pharmaceuticals Division. Alderley Edge is less than 20 miles from Manchester and in addition to the well-wooded Cheshire countryside which surrounds it, Alderley is within easy reach of the Derbyshire Peak District, the Lake District and the North Wales Coast. Staff working at Alderley live over a wide area but mainly in the Macclesfield and Alderley Edge/Wilmslow area.

In addition to salary ICI also operate a Productivity Bonus and Profit Sharing Scheme.

Anyone interested in applying for this vacancy (either male or female) should telephone or write (quoting reference IT/SH/SCC) to:-

Miss S C Carson,
Personnel Officer,
ICI Ltd, Central Toxicology Laboratory,
Alderley Park, Nr Macclesfield, Cheshire.
Phone - Alderley Edge E82711, extension 144.

Overseas candidates should only apply if they have a planned visit to the UK within the next two months. Closing date for applications. 23 April, 1979.

353(A)

PLANT BREEDING INSTITUTE MARIS LANE, TRUMPINGTON CAMBRIDGE CB2 2LQ HIGHER SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER CYTOGENETICS DEPARTMENT

A plant cell biologist, with experience in the preparation and culture of protoplasts and the regeneration of these into mature plants is required to participate in a programme assisted by the National Research Development Council to investigate transformation of plant cells using bacterials and other plasmids. The Officer will be expected to collaborate with other members of a team developing plasmids. It is expected that this Officer will be responsible for the plant cell cultures of the laboratory. Additional experience in molecular biology would be a distinct advantage.

Candidates should have a 1st or Upper 2nd Class Honours Degree in an appropriate biological science and at least two years' relevant postgraduate experience in cell biology.

The appointment will be as Higher Scientific Officer (£4,101 to £5,448 per annum) or Senior Scientific Officer (£5,154 to £6,898 per annum). At least four years relevant postgraduate experience is required for appointment as Senior Scientific Officer. Non-Contributory Pension Scheme.

Applications with curriculum vitae and the names and addresses of three referees should be sent to the Assistant Secretary (Estab.), quoting reference N.R.D.C. 50, by April 27.

Further details are available on request. 359(A)

THE UNIVERSITY OF LEEDS DEPARTMENT OF PURE AND APPLIED ZOOLOGY

Applications are invited
for the post of
DEMONSTRATOR
in the above Department.

The successful candidate will be required to assist with teaching in the honours degree in Zoology and Agricultural Zoology and to assist with research. Candidates should have a good honours degree in Zoology, Agricultural Zoology or Biology and should preferably also have, or be about to submit for, a Ph.D. degree. Preference may be given to applicants with research interests in applied insect physiology/biochemistry or agricultural entomology but applicants with other research interests in zoology or in applied zoology will also be considered. The appointment will be made for a fixed period of three years with effect from October 1, 1979.

Salary at an appropriate point on the 1B scale for Other Rel... Staff (£3,384 to £5,604) (under review), according to age, qualifications and experience.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 56/4/D. Closing date for applications: May 14, 1979.

299(A)

Whittington Hospital Research Assistant

(Basic Grade Biochemist Scale)
(£3,840 - £5,263 depending on experience in
National Health Service)

You will work in the Department of Chemical Pathology to join a team studying lipid peroxidation and other free-radical processes in biological and clinical material. Rotation into the main hospital service laboratory can be arranged so that the post may be suitable for training in clinical chemistry and acceptable for the probationary period of the basic grade biochemist grade.

The post is funded by the N.E. Thames Regional Health Authority for one year in the first instance but may be renewable for another two years. Short-listed candidates will be invited to visit the department.

Application forms from Hospital Personnel Department, Whittington Hospital, Highgate Hill, London N.19. Tel: 01-272 9873. Completed forms should be returned by 19th April, 1979. 316(A)

CAMDEN & ISLINGTON
AREA HEALTH AUTHORITY (TEACHING)

316(A)

CSIRO AUSTRALIA

Research Scientist Division of Textile Physics Ryde NSW

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field: Fabric Mechanics.

General: The Division carries out research and development in fibre physics, measurement technology applied to raw wool, and the physics of yarns and fabrics.

Duties: The appointee will carry out research in textile fabric mechanics with a view to understanding the bases of fabric performance, and therefore to improving properties such as wrinkling, drape, abrasion resistance and dimensional stability.

Qualifications: A relevant PH.D. degree or its equivalent together with subsequent research experience. Demonstrated ability to make and maintain appropriate industrial contacts would be an advantage.

Salary: Research Scientist or Senior Research Scientist. \$A15,422 to \$A22,405 p.a.

Tenure: Indefinite with superannuation.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 465/438 should reach:—

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 4th MAY, 1979.

Applications in U.S.A. and Canada should be sent to:—

The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A. 368(A)

THE BRITISH INDUSTRIAL BIOLOGICAL RESEARCH ASSOCIATION

GENETIC TOXICOLOGIST

THE BIBRA Research Laboratories are seeking a Genetic Toxicologist to initiate and lead a research team investigating problems relating to abnormalities of the genetic apparatus, and to assume responsibility for the laboratory's short-term carcinogenicity programme.

This is a senior position for a person with established scientific credentials and the employment package will reflect the responsibility.

Applications with a curriculum vitae should be addressed to:

The Secretary
The British Industrial Biological
Research Association
Woodmansterne Road
Carshalton, Surrey SM5 4DS.

321(A)

THE OPEN UNIVERSITY

Research Assistant in Biology

A research assistant is required for a project to investigate the role of physiological adaptation in populations of *Drosophila*.

Candidates should have a good first degree preferably in Genetics, and some experience in the handling of *Drosophila*.

The post is available initially for one year with the possibility that the grant may be renewed.

Commencing salary will be within the range £3,384—£3,883 per annum with USS benefits.

Application forms and further particulars are available, by postcard request please, from The Recruitment Office (JD3721/2). The Open University, P.O. Box 75, Walton Hall, Milton Keynes, MK7 6AL or telephone Milton Keynes 63404; there is a 24 hour answering service on 63868.

Closing date for applications: April 19. 291(A)

INORGANIC CHEMISTRY LABORATORY UNIVERSITY OF OXFORD

An S.R.C. postdoctoral appointment in organo-transition metal chemistry is available from August 1, 1979 for one/two years. The research would be suitable for those with a Ph.D. in either inorganic or organic chemistry or in X-ray crystallographic methods. Send enquiries or applications with curriculum vitae and names of referees to Dr M. L. H. Green (Tel: 0365 57387), Inorganic Chemistry Laboratory, South Parks Road, Oxford OX1 3QR. 306(A)

PLANT BREEDING INSTITUTE MARIS LANE, TRUMPINGTON CAMBRIDGE CB2 2LQ HIGHER SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER CYTOGENETICS DEPARTMENT

A molecular biologist is required to participate in a programme assisted by the National Research Development Council designed to transform genetically plant cells. In particular, this Officer will be responsible for the construction of vectors to facilitate the selection and detection of transformed plant cells. Consequently, experience in plasmid molecular biology and in DNA biochemistry is essential for this position. The Officer will be expected to collaborate with investigating and preparing plant cells for transformation.

Candidates should have a 1st or Upper 2nd Class Honours Degree in an appropriate biological science and at least two years postgraduate experience in molecular biology or related fields of biochemistry.

The appointment will be as Higher Scientific Officer (£4,101 to £5,448 per annum) or Senior Scientific Officer (£5,154 to £6,898 per annum). At least four years' postgraduate experience is required for appointment as Senior Scientific Officer. Non-Contributory Pension Scheme.

Applications with curriculum vitae and the names and addresses of three referees should be sent to the Assistant Secretary (Establishment), quoting reference NRDC 52, by April 27.

Further details available on request. 358(A)

NATURAL ENVIRONMENT RESEARCH COUNCIL British Antarctic Survey Advanced Ionospheric Sounder Project PERIOD APPOINTMENTS

The British Antarctic Survey has vacancies for a Physicist and an Electronics Engineer to participate in a major new research project to study the auroral ionosphere, using a recently-developed computer and microprocessor controlled high frequency radar known as the Advanced Ionospheric Sounder (AIS). The AIS is to be deployed at Halley station (76°S 27°W), Antarctica, and its operation will involve co-operation with University and Government laboratory groups both in UK and abroad. Successful candidates will be required to install, operate and maintain the equipment in Antarctica and will be encouraged to contribute to the research programmes. Applicants must be aged between 21 and 35, physically fit and male.

The Engineer, probably a graduate, will contribute to the evolution of the AIS system. He will be responsible for the system hardware and should also understand and be able to modify the software. The appointment will be for a period of approximately 33 months, commencing in the Summer of 1979. The successful candidate will undergo training, based in Cambridge, until sailing for Antarctica in October 1980 to spend one Antarctic winter at Halley station. He may be offered a further contract of one year to complete outstanding work in the UK.

The Physicist should be a graduate who has (or expects to achieve) a first or upper second honours degree in physics or computer science. He will direct the day-to-day scientific programme in the field and carry out research. The appointment will be for a fixed period of five years starting in Summer 1979. The successful candidate will be trained in Cambridge before sailing for Antarctica in October 1980 to spend two winters at Halley station. Suitable candidates can register for a higher degree at the University of Leicester and the remainder of the period is to enable the research to be written up at the University.

For further details of conditions of service and salary please write giving full details of qualifications and experience to:

The Establishment Officer,
British Antarctic Survey,
Madingley Road,
Cambridge CB3 0ET.

Closing date for applications: April 26, 1979.

Please quote reference BAS 10. 293(A)

Geology and Geophysics UNIVERSITY OF CALIFORNIA, BERKELEY

An Assistant Professorship in Geology is a vacancy to be filled during the 1979-80 academic year in the Department of Geology and Geophysics. Candidates must have an expertise which will contribute to an integrated programme of field and laboratory research and teaching. Individuals with interdisciplinary qualifications, experience and interests are encouraged to apply. Research emphasis may span such fields as metamorphic geology, structure-stratigraphy-sedimentology, or tectonics. The position will involve teaching and research supervision in the field. The Ph.D. degree is required.

Applications should be submitted by May 15, 1979 to:

T. V. McEvilly, Chairman
Geology and Geophysics
University of California
Berkeley, Ca 94720

and should include the names of three academic referees.

The University of California is an Affirmative Action employer. W34(A)

SOUTHAMPTON THE UNIVERSITY

DEPARTMENT OF PHYSICS

Applications are invited for the post of

LECTURER

in the Department of Physics. Candidates should have an active research interest in Quantum Physics and experience with the use of fields and groups. The person appointed will be expected to interact effectively with the Theoretical High Energy Physics group and to play a full part in the Department's programme of teaching in theoretical physics.

Salary scale £3,883 to £7,754 per annum plus U.S.S. The initial salary will depend on qualifications and experience. Further particulars may be obtained from Mrs E. C. P. Sears, Staffing Section, The University Southampton SO9 5NH to whom applications (7 copies from United Kingdom applicants) should be sent not later than May 18, 1979. Please quote reference number 1803/A. 253(A)

CHELSEA COLLEGE UNIVERSITY OF LONDON UNIVERSITY OF GHANA TEMPORARY LECTURESHIP IN GEOPHYSICS

An Inter University Council supported link scheme has existed since 1976 between the Geology Departments of Chelsea College and University of Ghana. The scheme includes the post of Lecturer in Geophysics under the Home Base Scheme and applications for this post are invited. The appointment is as Lecturer in the Geology Department, Chelsea College or a period of four years but the first three will be spent on secondment to the University of Ghana. Duties here will include undergraduate teaching of pure and applied geophysics and research in seismology, including the operation of a seismograph station that has been recording since 1976, and aspects of applied geophysics. Salary scale while at the home base is £3,883 to £7,754 per annum (under review) plus £502 London Allowance.

At the University of Ghana the salary scale Cedis 6,420 to 9,780 (£1=Cedis 5.50 approx.) would be supplemented under the British Expatriate Supplementation Scheme where appropriate. This scheme provides salary supplementation in the range £6,018 to £7,068 married and £3,504 to £4,296 single (under review), plus appointment grant, allowances for family passages, education allowance and children's holiday visit passages etc.

Further details and application forms from the Personnel Officer, Chelsea College, Friese Greene House, Chelsea Manor Street, London SW3 2TW. Applications to be received by May 18, 1979. 369(A)

INSTITUTE OF CANCER RESEARCH: JUNIOR TECHNICIAN required to join a research group at the Chester Beatty Research Institute, Fulham Road, S.W.3, investigating the metabolism of polycyclic hydrocarbons to derivatives that react with nucleic acids. Applicants for the post, which offers an opportunity of learning a variety of biochemical techniques, should have two 'A' levels in science subjects or O.N.C. and, preferably, some laboratory experience. Salary in scale £2,247 to £3,015 per annum depending on age and experience. Applications, in duplicate, with the names of two referees to the Secretary, Institute of Cancer Research, 34 Munster Place, London SW7 3NU, quoting ref. 301/B/66. 282(A)

SYNCHROTRON RADIATION EXPERIMENTS *Experimental Scientists*

The Daresbury Laboratory, an establishment of the Science Research Council situated in the north Cheshire countryside, is constructing a purpose built Synchrotron Radiation Source.

The source will begin to operate in April 1980 and will provide beams of intense electro-magnetic radiation ranging from the infra red through the visible and UV to the x-ray region. Research programmes involving Daresbury and University research workers will cover a very broad range of activities in Physics, Chemistry, Biology and related subjects.

DUTIES

Applications, from either sex, are invited from experimental scientists who are interested in collaborating with and/or providing technical support to the research programmes of the synchrotron radiation users. Successful candidates will join the Laboratory in-house group of scientists and technical staff and will be involved in the design, construction and installation of equipment for the research programmes and in the collection and analysis of data. An on-line data acquisition network is under construction and candidates interested in contributing to this latter aspect of the work are also invited to apply. Successful applicants must be prepared to work in a demanding multidisciplinary research environment and be capable of contributing new ideas to the development of the research facilities. The SRS will operate continuously over long periods and members of the in-house group will need to adapt their hours of working to the SRS running schedule.

QUALIFICATIONS

It is expected that successful candidates will have attained a good honours degree (or equivalent qualification) in a relevant field. In addition, experience in such fields as x-ray optics and spectroscopy, VUV spectroscopy, photoelectron and photon spectroscopy, photochemistry and photobiology is desirable for posts at the higher level.

POSTS AVAILABLE

Appointments will be made at both SO and HSO level on salary scales £2,839-£4,415 and £4,101-£5,648 respectively. It is possible that some fixed term research associate posts may also be available on a salary scale £3,695-£6,216. All the salary scales quoted are under review.

The Laboratory also offers a generous annual leave allowance, a non-contributory superannuation scheme and a flexible working hours scheme.

Closing Date: 1st May 1979

Please write, or telephone Warrington 65000 Ext. 467 for an application form, quoting reference No. DL/667/T to:

The Personnel Officer

DARESBURY LABORATORY
Science Research Council
Daresbury, Warrington WA4 4AD

298(A)

PARASITOLOGY RESEARCH

Pfizer Research in the U.K., which is part of an integrated international organisation, is located at Sandwich on the Kent Coast. Here in modern, well equipped facilities, which include a 300-acre research farm, about 500 scientists and support staff are engaged in the discovery and development of novel compounds for use in human and veterinary medicine.

We now require an innovative biologist to join the Parasitology department of our Agricultural Products R & D division to strengthen our research effort in the areas of endo- and ectoparasitic diseases of animals.

The appointment calls for a man or woman with up to three years post-doctoral research experience, who as well as being a creative scientist is also a good motivator and communicator, since our multi-disciplinary project management system requires close collaboration between specialists in various scientific disciplines.

Ideally, candidates will have a Ph.D in parasitology or entomology and should have specialist knowledge of physiology or biochemistry with an interest in the application of their subject to disease control. They should have a flexible attitude to and be interested in a long-term career in research.

The starting salary will reflect qualifications and experience and there is a good bonus potential. Pension, salary continuance and death benefit schemes are in operation and there is generous assistance with relocation expenses. Flexible hours are worked and the social/recreational facilities are first class.

Pfizer

Applications, which will be treated in confidence, giving details of qualifications, experience age etc., should be sent to:—
D. W. Sells
Personnel Manager
Pfizer Central Research
Sandwich, Kent.

362(A)

AN FORAS TALUNTAIS LAND RECLAMATION RESEARCH

Applications are invited for a RESEARCH POST in an expanding land reclamation programme, with particular emphasis on drainage. The post will be in the Western Research Centre at Creagh Station, Ballinrobe, Co. Mayo. The appointee will be engaged in the investigation, design, construction and evaluation of land reclamation works. The post will also involve work organisation and control, the use of machinery and materials and cost-benefit analyses.

Essential: An honours University Degree, or equivalent, in Engineering, Agricultural Engineering or Agricultural Science.

Desirable: (1) Suitable postgraduate training and/or experience.

(2) An interest and/or background in the Earth Sciences and Hydrology.

Applications also considered from 1979 Final Degree candidates.

Appointment up to and including Senior Research Officer level depending on qualifications and experience. Marriage and childrens' allowances. Non-contributory pension scheme and provision for widows' and orphans' pensions.

Application forms and further particulars by telephone request from Personnel Department, An Foras Taluntais, Headquarters, 19 Sandymount Avenue, Ballsbridge, Dublin 4. Telephone: 01-688188. Latest date for receipt of completed forms: Wednesday, April 25, 1979. W32(A)

MEDICAL RESEARCH COUNCIL CYCLOTRON UNIT has a vacancy for a SCIENTIST

to join a team working on the radiobiology of tumours and normal tissues, the aim being to improve the treatment of cancer. The successful candidate will investigate various aspects of the response of experimental tumours to fast neutrons, hyperthermia and chemotherapeutic agents. The work will involve animal and cell studies and the department has excellent facilities for both.

Knowledge of radiation biology and tumour biology will be an advantage although some training can be given. The minimum qualifications are a first or upper second class degree in an appropriate subject and a Ph.D. or equivalent. Several years' relevant postdoctoral research experience would be advantageous. This position offers a unique opportunity for someone with ability and enthusiasm for research of this nature.

Salary, according to age and experience, in the range £6,649 to £8,204 (inclusive of London weighting) plus six weeks annual leave.

Please write, giving qualifications and curriculum vitae, to:

Miss Alison Pires, M.R.C. Cyclotron Unit, Hammersmith Hospital, Duane Road, London W12 0HS. Tel: 01-743 4594, extn. 103. 319(A)

PLANT BREEDING INSTITUTE

MARIS LANE, TRUMPINGTON
CAMBRIDGE CB2 2LQ
SCIENTIFIC OFFICER
CYTOGENETICS DEPARTMENT

A Scientific Officer is required to provide support for a research programme on transformation of yeast and higher plants. The programme will include the construction of plasmid vectors suitable for selection and detection in yeast and plant cells. The officer should therefore have had some training in molecular genetics or biology or relevant areas of biochemistry.

Candidates should have an Honours Degree or equivalent in Biochemistry or an appropriate biological science, or an ordinary degree with relevant experience.

The appointment will be as a Scientific Officer (£2,839 to £4,415 per annum). The point of entry on the scale being determined in relation to qualifications and experience. Non-Contributory Pension Scheme.

Applications with curriculum vitae and the names and addresses of three referees should be sent to the Assistant Secretary (Establishment), quoting reference CYT 54, by April 27. Further details are available on request. 356(A)

UNIVERSITY OF NOTTINGHAM DEPARTMENT OF BIOCHEMISTRY AND NUTRITION Applications are invited for the post of DEMONSTRATOR

in the Food Science Laboratories of this Department which is accommodated at the University's School of Agriculture at Sutton Bonington.

This will be a two year appointment and the initial salary will be £3,384 per annum (under review).

Further particulars and forms of application, returnable not later than April 18, 1979, from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD. Ref. No. 679. 284(A)

UNIVERSITY OF CAPE TOWN

Applications are invited for the following posts:

SENIOR LECTURER IN

ORGANIC CHEMISTRY

This post falls vacant on July 1, 1979. Closing date for applications May 31, 1979.

LECTURERS IN

MICROBIOLOGY

Due to retirement of present staff members and expansion of the department, three lectureships will be vacant from January 1, 1980. Interest and experience in one or more of the following fields will be a strong recommendation: bacterial biochemistry; industrial microbiology; microbiology; genetics; molecular biology and virology. The posts may also be filled on a contract basis for two or three years with the possibility of either renewal or conversion into a permanent post. Closing date for application May 25, 1979.

GENERAL: Appointment to the above posts will be made, according to qualifications and experience, on salary scales ranging as follows:

FOR SENIOR LECTURER:

From R10,144 to R13,489 p.a.

FOR LECTURER:

From R7,554 to R11,007 p.a.

(Improvement to these salary scale is imminent).

Applicants should submit a curriculum vitae stating present salary, experience, research interests and publications if any, the date duty could be assumed, and the names and addresses of three referees.

Further information concerning the positions and general conditions of service should be obtained from the Registrar, Room 10, University of Cape Town, Private Bag 1, Rondebosch 7700, South Africa.

The University's policy is not to discriminate in the appointment of staff or the selection of students on the grounds of sex, race, religion, or colour. Further information on the implementation of this policy is obtainable from the Registrar. W25(A)

UNIVERSITY OF NAIROBI KENYA

Applications are invited for the posts of

LECTURER

IN DEPARTMENT OF GEOGRAPHY

Applicants should hold postgraduate qualifications in Geography preferably at Ph.D. level. The Department seeking to appoint geographers with research interests and competence specifically in any of these areas: Biogeography (especially in the geography of soils), Climatology, Economic geography, Transport geography, Urban geography and the Geography of resources (with special interest in Remote Sensing). The appointees will also be expected to participate in field courses and in the teaching of practical geography to the different classes of undergraduates and undertake supervision of postgraduate students in the specialised areas besides undertaking research. Salary Scale: K£2,016 to K£3,312 p.a. (K£1=£1.32 sterling). The British Government may supplement salaries in range £4,278 to £4,818 p.a. (sterling) for married appointees (£2,730 to £3,156 p.a. (sterling) for single appointees (reviewed annually and normally free of all tax) and provide children's education allowance and holiday visit passages. F.S.S.U. family passages; various allowances. Detailed applications (2 copies) including a curriculum vitae and naming referees should be sent by airmail by May 10, 1979 to the Registrar (Recruitment and Training), University of Nairobi, P.O. Box 30197, Nairobi Kenya. Applicants resident in U.K. should also send 1 copy to the University Council, 90-91 Tottenham Court Road, London W1P 0D. Further particulars may be obtained from either address. 370(A)

UNIVERSITY OF WALES UNIVERSITY COLLEGE OF SWANSEA

RESEARCH DEMONSTRATOR

Applications are invited for the vacancy of Research Demonstrator in the Department of Geology. Applicants should either be in possession of a B.Sc. or have such a degree near to completion. A background in petrology, geochemistry and/or structural geology would be preferred.

The appointment, which will be for one year in the first instance renewable on an annual basis for a maximum of three years, will be on a scale up to £4,382 per annum, together with J.S.S./U.S.D.P.S. benefits.

Further particulars and application forms (two copies) may be obtained from the Personnel Officer, University College of Swansea, Singleton Park, Swansea SA2 8PP, to whom they should be returned by Friday, April 17, 1979. 338(A)

UNIVERSITY OF ZAMBIA

Applications are invited for the following posts in the School of Medicine.

- ASSOCIATE PROFESSOR/
SENIOR LECTURER/

A medical differential of \$1,200 per annum may be paid to clinical appointees (£1 sterling = £1.61). The British Government may supplement salaries as follows: Non-clinical academic staff, in range £4,350 to £5,952 per annum (sterling) or married appointees or £1,968 to £3,366 per annum for single appointees, clinical academic appointees—in range £4,566 to £6,042 per annum (sterling) or married appointees or £1,980 to £3,456 per annum (sterling) for single appointees; Chief Technician, by £4,182 per annum (sterling) for married appointees or £1,986 per annum (sterling) for single appointees, and provide children's education allowances and holiday visit passages. Family passages, baggage allowance, superannuation, medical aid scheme, regular overseas leave.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees should be sent by airmail to Registrar, University of Zambia, P.O. Box 237, Lusaka, Zambia, by May 7, 1979.

Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address 290(A)

Wellcome

Department of Experimental Immunobiology

Immunologist

£5000 - £7800*

We seek a post-doctoral scientist to work on a programme concerned with the development of new immunological adjuvants and the analysis of the mechanisms of adjuvant action.

The appointment will be for a period of 2-3 years in the first instance and applicants should be able to provide evidence of an innovative approach to immunobiological research.

Senior Technician

£3350 - £4750*

We seek a senior technician to work in a research team involved with immunological studies in immunostimulation and new vaccine development.

Previous experience in biochemistry and immunology and a knowledge of methods involved, including working with animals, would be an advantage.

The Laboratories are situated in pleasant parkland surroundings within easy reach of Central London. Conditions of employment are excellent and include subsidised canteen, pension scheme, 4 weeks' holiday, generous relocation expenses where appropriate, and sports and social facilities.

*Salary will be in the range indicated with a review on May 1, 1979.

For an application form please write, giving brief details, to the Personnel Manager, The Wellcome Research Laboratories, Langley Court, Beckenham, Kent BR3 3BS.

330 (A)

JUNIOR TECHNICIAN/ TECHNICIAN

(Ref. 198/199/79)

required to assist with clinical studies on serum factors with tumour marker potential. Initially, the work will involve routine assays including radioassays. Previous experience in immunological techniques an advantage. ONC/HNC/Degree required. Salary, depending on age, qualifications and laboratory experience within range £2,800 to £3,300 or £3,500 to £4,900. For application form and job description, please telephone Mrs Nelson, Imperial Cancer Research Fund, Lincoln's Inn Fields, WC2 on 01-242 0200, ext 305 345(A)

ST GEORGE'S HOSPITAL MEDICAL SCHOOL

(University of London)

RESEARCH TECHNICIAN

required for research programme in the Child Health Department. Duties involve programmes in infant nutrition, biochemical genetics, endocrinology and lipid metabolism in children. HNC or degree in biochemistry or related subject required. Emoluments up to £3,995 per annum (under review) according to experience. Informal enquiries to Dr N. Carter (01-672 1255, Ext 4171). Application forms available from the Establishment Officer, St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE. 339(A)

EDITORIAL SERVICES CONTROLLER

We need an experienced, literate and adaptable Editorial Controller to work in our Higher and Further Education division, managing a wide variety of typescripts in subjects ranging from undergraduate science to semi-technical hobbies. The job involves working closely with the Further Education, Published, copy-editing and proof-reading, as well as dealing with authors, freelance staff, and our own production staff. Accuracy, and the ability to rewrite where necessary are important. Training will be provided for a person with the required academic and work record.

We are based at Basingstoke, close to the M3. The right person will be offered a competitive salary, and will be entitled to 20 days' holiday per year. We also have a subsidised bar, canteen, social club, pension scheme, and free transport to and from the town centre.

Send your application in handwriting, along with a detailed curriculum vitae, to Sheldagh Browne, Personnel Manager, The Macmillan Press Ltd., 4 Little Essex Street, London WC2R 3LF. 333(A)

Experienced Research Chemist Semi-Synthetic Antibiotics

Europe-based

£15,000-£25,000

On behalf of clients based in Continental Europe, we seek a synthetic or process-development chemist with in-depth practical experience of semi-synthetic antibiotic synthesis.

He or she will take up an important new research appointment and, as well as playing a leading role in fundamental research, will be expected to contribute both ideas and direction to the company's development programme in this field.

The *ideal* candidate will probably be in the age range 28-35, and possess both wide knowledge and at least three years' practical experience, in industry, of semi-synthetic penicillin and/or

cephalosporin synthesis. This experience may have been gained either in fundamental research or in process development.

We recognise that there are few people with the specialist knowledge and experience we seek. Accordingly, our client aims to provide a salary and benefits package that should prove highly attractive to any suitably qualified candidate.

Please write in confidence for an application form and further information, or 'phone if you would like to discuss the appointment further before applying.

AGRICULTURAL RESEARCH COUNCIL INSTITUTE FOR RESEARCH ON ANIMAL DISEASES

Biochemist/Molecular Biologist

Required for studies on scrapie, ageing and the nature of virulence determinants in pathogenic bacteria. Among the main lines of research will be the physical characterisation of the small DNA species recently isolated from scrapie brain and the establishment of the relationship of this DNA to the genome of the scrapie agent. Also molecular approaches to the problem of ageing as applied to loss of production in farm animals.

Qualifications: A 1st or Upper 2nd class honours degree in Biochemistry or Biological Science or Chemistry.

Appointment as Scientific Officer (£2,839 to £4,415 or Higher Scientific Officer (£4,101 to £5,448) according to qualifications and experience. At least 2 years' relevant postgraduate experience is required for H.S.O. Non-contributory pension scheme.

Application Forms from: Secretary, Institute for Research on Animal Diseases, Compton, Nr. Newbury, Berks., quoting ref. 305. 325(A)

THE UNIVERSITY OF LEEDS DEPARTMENT OF EARTH SCIENCES Experimental Officer— Electron Probe Microanalysis

Applications are invited from Ph.D. graduates and other suitably qualified persons for a post of EXPERIMENTAL OFFICER concerned with operation and development in the electron probe microanalysis laboratory (JEOL JXA 50A). The post carries day-to-day responsibility for training and maintenance in the laboratory, and offers the opportunity to participate in major research projects involving the electron probe. It is hoped to make an appointment to the post as soon as possible.

Salary at an appropriate point on the IA scale for Other Related Staff (£3,883 to £6,555) (under review), according to age, qualifications and experience.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 49/12/D. Closing date for applications May 8, 1979. 315(A)

UNIVERSITY OF ABERDEEN LECTURESHIP IN ZOOLOGY

Applications are invited for the above post.

Salary on scale £3,883 to £7,754 per annum, with appropriate placing. Superannuation and removal expenses.

Further particulars from the Secretary, The University, Aberdeen, with whom applications (two copies) should be lodged by April 27, 1979. 302(A)

UNIVERSITY OF RHODESIA

Applications are invited for the following posts:

LECTURESHIPS/ SENIOR LECTURESHIPS IN ENGINEERING

Applicants should have an engineering degree and appropriate postgraduate experience in at least one of the following specialist fields: **Civil Engineering**, Materials, Water Engineering, Geotechnical; **Electronic and Power Engineering**, Electric Power Systems, Electrical Machines, Electromagnetics, Electrical Networks, Control Systems; **Mechanical Engineering**, Dynamics, Thermodynamics, Heat Transfer, Mechanical Design, Fluid Mechanics; **Materials Science**, Metallurgy or Ceramics.

Salary Scales (Approx. Stg. equivs). Professor, £10,055 by 378 to £11,941; Senior Lecturer, £7,311 by 284 to £8,163 by 301 to £9,668; Lecture Grade I, £6,632 by 249 to £7,621; Lecture Grade II, £4,094 by 215 to £5,169 by 249 to £6,414. Subject to permission, earnings of up to approximately £3,400 per annum for consultancy may be retained in full.

Both Permanent Pensionable Term and Short-term Contracts are available. Unless born in Rhodesia, ex-patriate on contract are exempt from military service.

Further particulars and application procedure from the Association of Commonwealth Universities (Appts 36 Gordon Square, London WC1H 0PF).

Closing date for receipt of applications is **May 31, 1979.**

British subjects considering applying for posts in Rhodesia are urged to consult the Foreign and Commonwealth Office (Telephone 233 8727) or their nearest British Consular Office.

UNIVERSITY OF
EDINBURGH
DEPARTMENT OF GENETICS
POSTDOCTORAL
RESEARCH FELLOW

Postdoctoral position, supported by the S.R.C., is available for two years to collaborate with Dr J. O. Bishop in the molecular cloning of nuclear protamine DNA sequences in the trout. Cloned cDNA sequences are already to hand. Starting date not later than June 30, 1979. Salary £4,382 per annum.

Applications with curriculum vitae and names of two referees should be sent to the Secretary to the University, Old College, South Bridge, Edinburgh EH8 9YL, not later than April 27, 1979. Please quote Reference 5016. 349(A)

UNIVERSITY OF NAIROBI
KENYA

Applications are invited for the post of

PROFESSOR
IN DEPARTMENT OF
PHYSICS

Applicants must have a Ph.D. degree in Physics. They should also have considerable years of University teaching and research experience as evidenced by publications in internationally reputable journals. Active areas of research in the department include Theoretical Physics, Ionospheric Physics, Solid State Physics, Applied Geophysics and Palaeomagnetism. Specialisation in one of the fields would be an added advantage. Salary scale KSh 4,632 to KSh 5,562 per annum (KSh equals £1 32 Sterling). The British Government may supplement salary by £6,552 per annum (Sterling) for married appointee or £4,644 per annum (Sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowance and holiday visit passages S.S.F. or P.S.U.; family passages, medical and scheme; housing allowance, various allowances. Detailed applications (two copies) including a curriculum vitae and naming three referees should be sent by airmail not later than May 10, 1979 to the Registrar (Recruitment and Training), University of Nairobi, P.O. Box 30197, Nairobi, Kenya. Applicants resident in U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address.

326(A)

UNIVERSITY OF DURHAM
DEPARTMENT OF
EXTRA-MURAL STUDIES
Applications are invited for the post of
STAFF TUTOR

in Biological Sciences (Zoology) to develop further a wide range of courses for both the general public and specialist groups. Experience in teaching adults is desirable but not essential.

Salary on the scale £3,883 to £7,754 per annum (under review) plus superannuation.

Applications (three copies) naming three referees should be sent by April 21, 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. 281(A)

ST GEORGE'S HOSPITAL
MEDICAL SCHOOL
(University of London)
TECHNICIAN GRADE 4

urgently required in Structural Biology Department for a three-year Cancer Research Campaign project, to work on the analysis of cell surface molecules, using immunological methods in embryonic cells. Experience of tissue culture techniques and/or immunological methods desirable. Salary in the range £2,955, £3,042, £3,132 (under review) plus £275 London allowance. Application forms and further particulars available from the Establishment Officer, St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE.

342(A)

Exciting Opportunities in Reactor Physics Hinkley Point Power Station

Two interesting opportunities have arisen for experienced Reactor Physicists to take charge of the operation of the four reactors at Hinkley Point Power Station.

The posts are part of the Reactor Physics Department which consists of a team of technical staff responsible for the safe, effective and economic operation of the two Magnox Reactors in the 'A' Station, operational since 1965, and the two Advanced Gas Cooled Reactors in the 'B' Station, commissioned last year.

The more senior post will be assigned to duties on the 'A' Station. He or she will take part in the daily management of the reactors and in the development of medium and long term strategies. Duties also include safety analysis work which is a continuing and important part of the Department's work.

The second person will work at the 'B' Station and will be mainly concerned with the daily management of the reactors.

Applicants for both positions should possess a degree or equivalent qualification in Physics, Mathematics or Engineering. Experience in nuclear design or research would be relevant and an advantage.

Salary will be in the range £4110-£7060 plus a self-financing productivity payment. Terms and conditions are excellent and fringe benefits include relocation assistance where appropriate.

If you are interested, please write for an application form AF/1 from the Personnel Manager, Bedminster Down, Bridgwater Road, Bristol BS13 8AN. Please complete and return, quoting vacancy number 106/79/N.

357(A)

Central Electricity
Generating Board
South Western Region

PRESTON
POLYTECHNIC

Applications are invited for the following appointment.

SENIOR LECTURER
IN BIOLOGY

Preference will be given to applicants specialising in Ecology or Medical Laboratory Science.

Salary scale (under review) £6,051 to £7,065 to £7,572.

Application forms and further particulars may be obtained from the Chief Administrative Officer (Staffing), Preston Polytechnic, Corporation Street, Preston PR1 2TQ, to whom completed applications should be returned by April 23.

344(A)

MEDICAL RESEARCH
COUNCIL
CYCLOTRON UNIT
requires a
SCIENTIST

to investigate the effects of hyperthermia on mammalian cell membranes. The successful candidate will join a group which is investigating various aspects of the response of cells and tissues to elevated temperatures, with a view to using hyperthermia to treat cancer. It is essential that applicants already have research experience in membrane biochemistry. An appropriate biological degree is required together with a Ph.D. or equivalent research experience. The appointment will be for one year.

Salary, according to age and experience, in the range £5,081 to £6,530 (inclusive of London Weighting).

Please write, giving qualifications and curriculum vitae, to Miss A. Piles, Medical Research Council Cyclotron Unit, Hammersmith Hospital, Duane Road, London W12 0HS (Tel 01-743 4594, extn 103).

355(A)

THE EDINBURGH SCHOOL OF AGRICULTURE
DEMONSTRATOR—GRADE III OFFICER

AGRICULTURAL BIOCHEMISTRY DEPARTMENT (Ref 189N)

A demonstrator is required to assist in teaching degree and diploma students in agricultural biochemistry, animal nutrition and applied biology. An opportunity will also be available to carry out research in an approved area.

Candidates must possess a good honours degree in Agricultural Science, Biochemistry, Biology or related subject. Preference will be given to candidates with a postgraduate qualification and a knowledge of animal nutrition.

Appointment will be made on the scale of Grade III or Grade IV according to qualifications. Grade IV, £2,598 to £3,924, Grade III, £4,178 to £6,898. Non-contributory pension scheme.

For further particulars and application forms write to The Secretary, The East of Scotland College of Agriculture, West Mains Road, Edinburgh EH9 3JG. Closing date for return of completed applications April 30, 1979.

351(A)

POSTDOCTORAL position available to study protein mobility in cell membranes and model systems. Previous experience with optical spectroscopy would be advantageous. The position is funded by the Swiss National Science Foundation with a salary of approximately S Fr. 35,000 to S Fr. 40,000 per year, depending on age and experience. Please send applications with names of two referees to Dr R. J. Cherry, Laboratorium für Biochemie, Eidgenössische Technische Hochschule, ETH-Zentrum, CH 8092 Zurich, Switzerland.

W35(A)

UNIVERSITY OF OXFORD
DEPARTMENT OF THEORETICAL PHYSICS
RESEARCH ASSISTANT
IN THEORETICAL NUCLEAR PHYSICS

Applications are invited for the post of Research Assistant to the Nuclear Theory Group. The post is funded by the Science Research Council to support ongoing research in nuclear structure and heavy ion reactions. The appointment is temporary for one to three years from October 1, 1979.

The salary is on the Research Support Scale (A) currently £3,883 to £6,555 per annum with USS membership. The applicant should not exceed the age of 31 in the first year of the appointment.

Applications with the names of 2 referees to the Secretary, Department of Theoretical Physics, 1 Keble Road, Oxford, by April 27, 1979.

361(A)

**Directorate of Fisheries Research
Environment Protection Division,
Burnham on Crouch**

Sedimentologist

... to join a team of scientists assessing the effects of effluent discharges on the marine environment, and in particular the sea bed. The work will involve planning and participating in experiments, collecting samples from Ministry research vessels, organizing laboratory work, and analysing computer data to assess the chemical and physical effects of waste disposal on the marine environment. In addition, the successful candidate will represent the Division in specialist working groups.

Candidates, normally aged under 27, should have a good honours degree or equivalent in geology, geography, earth sciences or a closely related discipline. Experience of marine sedimentology is highly desirable. *Final Year Students may apply.*

Appointment as Scientific Officer (£2840 - £4410; under review) with starting salary according to qualifications and experience. Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by 1st May 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). *Please quote ref: SB/46/AD.*

CIVIL SERVICE

KING'S COLLEGE LONDON
University of London
APPOINTMENT OF PRINCIPAL

The Principal of King's College, Sir Richard Way, KCB, CBE, is due to retire on July 31, 1980. It is intended that a successor should be appointed from August 1, 1980.

The Principal is the chief academic and administrative officer of the College.

The salary is negotiable and living accommodation is provided.

Persons interested in being considered for this appointment, or wishing to suggest names, are invited to write in confidence not later than April 23, 1979, to the Chairman of the Delegacy, the Rt. Hon. Earl Jellicoe, DSO, MC, at King's College London, Strand, London WC2R 2LS, from whom further particulars are available.

308(A)

STATE UNIVERSITY OF UTRECHT
Biological Faculty
The Netherlands

Applications are invited for the position of
PROFESSOR
in Palaeobotany and Palynology.

Requirements: A Ph.D. degree in biology or geology with specialisation in palaeobotany, with emphasis on micropalaeobotany, and ability for productive research as well as leadership potential.

Persons who meet these qualifications and like to be considered as candidates or those wanting to mention likely candidates are requested to contact Dr H. O. Voorma, Department of Molecular Cell Biology, Padualaan 8, 3584 CH Utrecht, Netherlands. W29(A)

**PURDUE UNIVERSITY
RESEARCH ASSOCIATES
THEORETICAL
CHEMISTRY**

Two openings exist for theoretical chemists to study molecular liquids and solutions with applications in organic chemistry. A Ph.D. in chemistry or physics and background in computing and molecular quantum or statistical mechanics are required.

Start anytime in 1979. Salary is \$12,000/year. Appointments are renewable.

Send vitae and names of references to: Prof. Wm. L. Jorgensen, Department of Chemistry, Purdue University, West Lafayette, Indiana 47907, U.S.A. An equal opportunity/affirmative action employer.

W19(A)

**UNIVERSITY OF
QUEENSLAND
Australia
TEMPORARY LECTURER
IN GEOGRAPHY**

Applicants should have a higher degree and tertiary teaching experience.

The appointee will take responsibility for teaching basic courses in Remote Sensing and Cartography and an advanced course in Geomorphology. (Quote Ref. No. 13079) April 30, 1979.

Salary: \$A15,786 to \$A20,737 per annum. Other Benefits: Single air fare for appointee only to Brisbane.

Additional information and application forms are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

322(A)

**UNIVERSITY OF
AUCKLAND
New Zealand**

Applications are invited for the following full-time teaching positions. Conditions of appointment and method of application are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications, in accordance with "Method of Application", will be accepted at any time up to **May 14, 1979** unless otherwise stated. Commencing salaries in accordance with qualifications and experience will be established within the appropriate scale. The scale for Lecturers is NZ\$11,529 per annum rising by annual increments to NZ\$14,250 per annum. In normal circumstances, a Lecturer whose services have proved satisfactory to the Council may expect in due course to be given the status of a Senior Lecturer, salary maximum NZ\$16,780 per annum. At present all salaries are supplemented by a General Wage Order of NZ\$365 per annum.

**Biochemistry
LECTURESHIP**

Applicants should have a first degree in biochemistry or chemistry and suitable postgraduate qualifications in biochemistry. Preference will be given to candidates who have completed a period of postdoctoral research.

**Numerical Analysis
LECTURESHIP**

Closing Date: July 15, 1979. For 1979 this position is within the Computational Mathematics Unit of the Department of Mathematics, but from 1980 it will be within the newly formed Department of Computer Science. Applications should have qualifications within any field of numerical analysis.

347(A)

**KENYATTA UNIVERSITY
COLLEGE—KENYA
(Constituent College of
University of Nairobi)**

Applicants are invited for the post of
**ASSOCIATE PROFESSOR
IN THE BOTANY
DEPARTMENT**

Applicants must have a Ph.D. degree in Botany and considerable experience at University level, at least to Senior Lecturer level. Further qualifications in Education or experience in the training of graduate teachers would be advantageous. They should also provide evidence of successful research activity through publications in reputed journals. The appointee will be expected to teach in the B.Ed. and M.Sc. programmes and to carry out and supervise research in his/her area of specialisation. He/she will also be expected to be capable of providing academic and administrative leadership in the department. Salary scale: K£3,864 to K£4,488 per annum, (K£1 Sterling equals £1.32). The British Government may supplement salary by £5,784 per annum (sterling) for married appointee or £3,876 per annum (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages: subsidised housing; S.S.F. or F.S.S.U.; non-contributory medical aid scheme. Detailed applications (two copies) with curriculum vitae and naming three referees should be sent by airmail to the Registrar, Kenyatta University College, P.O. Box 43844, Nairobi, Kenya by May 8, 1979. Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address.

328(A)

**UNIVERSITY COLLEGE
OF SWAZILAND**

Applications are invited for the post of

**LECTURER IN
AGRICULTURAL
ENGINEERING**

in the Department of Land Use and Mechanisation. Candidates should possess a Degree or Diploma in Agricultural Engineering. Formal training in teaching Agricultural Engineering at College level would be an advantage. The appointee will be expected to provide lectures on Farm Machinery and Crop Mechanisation to Degree and Diploma students and practical demonstrations relevant to these courses. Salary scale: L4,140 to L7,860 per annum (£1 sterling equals L1.71). The British Government may supplement salary in range £1,650 to £1,986 per annum (sterling) for married appointee or £408 to £780 per annum (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. If appointment is for a limited period, a 25 per cent gratuity is paid in lieu of superannuation for the first two years of service; 27½ per cent for the second two years. A 10 per cent inducement allowance is payable to expatriates not qualifying for supplementation from other source. Education allowance; medical aid scheme; reasonable rented accommodation; family passages; biennial leave. Detailed applications (two copies) with curriculum vitae and naming three referees to be sent by May 9, 1979 to the Registrar, University College of Swaziland, Private Bag, Kwaluseni, Swaziland. Applicants resident in the U.K. should send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address.

327(A)

Guy's Hospital Medical School. Experienced **SECRETARY** required from June to work for Professor and Unit of Gastroenterology. Applicants must be competent shorthand-typists. Salary according to experience and qualifications. Apply in writing, stating age and giving details of qualifications and experience, to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. G.R.1.

320(A)

UNIVERSITY OF STIRLING

DEPARTMENT OF BIOLOGY POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the post of postdoctoral research assistant to work on an N.E.R.C.-funded project to study the productivity of oligochaete worms in the Forth estuary.

The appointment will be for 2½ years, on the Research and Analogous Staff Scale 1A, £3,883 to £4,382 (subject to review), with the starting date to be arranged.

Further details are available from the Secretary, University of Stirling, Stirling FK9 4LA to whom applications should be submitted, together with the names of two referees, by April 17, 1979. 312(A)

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF BOTANY

SENIOR

RESEARCH ASSISTANT

Applications are invited for the post of Senior Research Assistant to work on the production of a new Check List of British Ascomycetes (including lichen-forming species) under the joint direction of Dr G. N. Greenhalgh (Liverpool University) and Dr D. L. Hawksworth (Commonwealth Mycological Institute, Kew). The work involves both a critical assessment of existing records and revisionary work, and the person appointed will divide their time between Liverpool University and the Commonwealth Mycological Institute. Candidates should have some experience in the field of taxonomy and nomenclature, preferably, though not necessarily, with fungi and lichens and should have, or expect to obtain, their PhD before taking up the appointment.

The project will be financed by the SRC for three years. The initial salary will be within the range £3,883 to £4,382 per annum (under review).

Applications (three copies), together with the names of two referees, should be received not later than April 30, 1979, by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX from whom further particulars may be obtained. Quote ref RV/344/N 297(A)

THE WEST OF SCOTLAND AGRICULTURAL COLLEGE ADVISORY AND DEVELOPMENT SERVICE

Post of

SENIOR

EXPERIMENTAL OFFICER (Grade II)

Glasshouse Investigational Unit for Scotland

Applications are invited from suitably qualified persons for the post of Senior Experimental Officer, Grade II. Preference will be given to Honours graduates in horticulture or a closely related discipline. Candidates will be expected to have appreciable post-graduate experience of glasshouse experimental and development work and preferably some knowledge of commercial glasshouse production. Duties will include the initiation and implementation of experimental programmes and responsibility for the day-to-day supervision of work at the Unit.

Salary, Grade II, £6,447 rising to £7,651. Application forms and conditions of appointment may be obtained from the Secretary, The West of Scotland Agricultural College, Auchincruive, Avr 2A6 5HW, with whom applications should be lodged not later than May 4, 1979. 301(A)

Laboratory Technicians Pharmaceutical Development

Hoechst is one of the world's leading chemical and pharmaceutical manufacturers and a policy of continuous development has created the following opportunities in our research and development laboratories at Milton Keynes.

We are currently seeking experienced technicians for the following areas:—

To provide technical support in the development of animal feed products. The successful candidate will develop and improve analytical methodology and perform quality control assays, process investigations and stability evaluation for a range of medicated animal feed products. Candidates should have experience of working in an analytical laboratory and preferably be qualified to HNC level in Chemistry.

To assist with analytical aspects of the development of pharmaceutical products. The successful candidate will be primarily involved with the testing and stability evaluation of experimental pharmaceutical dosage forms using a wide variety of physical and chemical testing methods. Candidates should have some laboratory experience and preferably be qualified to GCE 'A' level in chemistry.

The posts carry good salaries, a free private health scheme, subsidised restaurant meals, at least 4 weeks' holiday a year and good sports facilities.

Please write or phone for an application form to:—

Mrs. Sheila Matthews, Personnel Dept., Hoechst UK Ltd., Walton Manor, Walton, Milton Keynes MK7 7AJ. Tel: Pineham 5068.

Hoechst

363(A)

UNIVERSITY OF JUBA SUDAN

Applications are invited for the following posts:

1. PROFESSOR/
ASSOCIATE PROFESSOR/
LECTURER IN ANATOMY.
2. PROFESSOR/
ASSOCIATE PROFESSOR/
LECTURER IN PHYSIOLOGY.
3. PROFESSOR/
ASSOCIATE PROFESSOR/
LECTURER IN
COMMUNITY MEDICINE

Salary scales (excluding cost-of-living allowance). Professor £55,460 per annum, Associate Professor £54,030 to £54,550 per annum, Lecturer £51,500 to £53,500 per annum (£51=£1.23 sterling). The British Government may supplement salaries in range £3,894 to £4,542 per annum (sterling) for married appointees or £1,830 to £2,310 per annum (sterling) for single appointees (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages, various allowances, superannuation scheme, annual overseas leave.

Detailed applications (2 copies) including a curriculum vitae and naming 3 referees, should be sent by air mail to the Vice-Chancellor, University of Juba, P.O. Box 82, Juba, Sudan, by May 8, 1979.

Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. 282(A)

AN X-RAY CRYSTALLOGRAPHER

OR ELECTRON MICROSCOPIST

is sought to take part in a structural study of crystals of SV-40 virus. This postdoctoral position begins May 1, 1979. For a crystallographer, experience with proteins is desirable, but not essential. For an electron microscopist, interest in 3-dimensional reconstruction or in 2-dimensional arrays is preferred. Send a resume and two letters of recommendation to: Eaton Lattman, Department of Biophysics, Johns Hopkins School of Medicine, Baltimore, MD 21205, USA. (301) 955-8715. Johns Hopkins is an equal opportunity/affirmative action employer. W23(A)

EAST MALLING

RESEARCH STATION

PHYSIOLOGY DEPARTMENT

A BIOCHEMIST to join the Hormone Unit for work in support of a programme of biochemical research on plant hormones controlling the growth and cropping of fruit trees.

Applications are invited from those with honours degree in Chemistry or Biochemistry or an ordinary degree, or H.N.C., with relevant experience.

Appointment in Scientific Officer grade (£2,839 to £4,415) starting salary depending on qualifications and experience.

Details and application forms from Assistant to the Secretary, East Malling Research Station, East Malling, Maidstone, Kent. 324(A)

UNIVERSITY OF ZAMBIA

Applications are invited for the post of

SENIOR LECTURER/

LECTURER IN THE

DEPARTMENT OF BIOLOGY

Applicants must have a Ph.D. or equivalent. The areas of research interest given preference are comparative plant and animal metabolism, enzymology or morphogenetic biochemistry. Preference will be given to those with experience in University lecturing and enzymological studies. The appointee will be expected to take up duties as soon as possible and be responsible for the teaching of general Physiology and Biochemistry in component courses as well as conducting an advanced biochemistry course in the final year of the B.Sc. programme.

Salary scales. Senior Lecturer K7,638 to K8,016 per annum; Lecturer, K5,504 to K7,608 per annum (£1 sterling=K1.61). The British Government may supplement salary in range £2,922 to £4,350 per annum (sterling) for married appointee or £930 to £1,968 per annum (sterling) for a single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages, baggage allowance; superannuation; medical aid scheme; regular overseas leave.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees should be sent by air mail to Registrar, University of Zambia, P.O. Box 2379, Lusaka, Zambia, by May 7, 1979.

Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 287(A)

ROYAL DENTAL HOSPITAL OF LONDON

School of Dental Surgery
(University of London)

LECTURESHIP (RESTRICTED TENURE) IN ANATOMY IN RELATION TO DENTISTRY

Applications are invited for the post of Lecturer in Anatomy tenable for up to three years commencing on September 1, 1979.

The Department of Anatomy in relation to Dentistry is responsible for teaching human anatomy, histology and dental anatomy to dental students. This appointment will be at a junior level and the duties will include teaching part or all of these subjects. Previous experience in human anatomy would be a considerable advantage. Adequate research facilities are available, including histology, histochemistry, tissue culture, electron microscopy, etc.

The Department is situated in a modern building shared with St George's Hospital Medical School in Tooting, London, S.W.17.

Salary will be at the appropriate point on the scale £3,906 per annum (currently under review), plus London Allowance of £502 per annum, with superannuation under U.S.S.

Further details may be obtained from Dr A. F. Hayward, Department of Anatomy in Relation to Dentistry, Royal Dental School, Jenner Wing, St George's Hospital Medical School, Cranmer Terrace, London, S.W.17, telephone 01-672 1255 ext. 4633, to whom applications with the names of three referees should be submitted before May 5, 1979. 371(A)

CHEMICAL TOXICOLOGIST

TENURE-TRACK ASSISTANT
OR ASSOCIATE PROFESSOR

Available: August 1979

Ph.D. required

Previous training and research experience in toxicology is essential. Applicant should have a strong background in chemistry and biochemistry. The successful applicant will be expected to develop a strong research program in toxicology which would attract continued outside funding in support of our M.S. chemistry and Ph.D. biomedical sciences degree programs. Responsibilities include undergraduate teaching in the individual's specialty as well as graduate courses in toxicology.

Send resume, research project proposals, and three letters of recommendation to Dr Frank E. Scully, Jr., Chairman, Search Committee, Department of Chemical Sciences, Old Dominion University, Norfolk, VA 23508.

Applications must be received no later than April 30, 1979. Applications from all qualified individuals are invited. An Affirmative Action/Equal Opportunity Employer. W40(A)

UNIVERSITY OF WARWICK LECTURESHIP IN MICROBIOLOGY

Applications are invited for a new post tenable from October 1, 1979 in the Department of Biological Sciences. Teaching will be within the degree courses taught in the Department, the precise area depending upon the interests and experience of the candidate and requirements of the Department. The successful applicant will be appointed to the Microbiology Research Group led by Professor R. Whittenbury; and will be expected to undertake research which complements one or more of the existing projects. Applications from candidates with experience in or a particular interest in, the morphogenesis and differentiation of prokaryotes and who have skills in molecular biological, genetic and/or genetic manipulation techniques, will be particularly welcome. Initial salary will be within the first four points of the Lecturer scale: £3,883 to £4,631 to £7,754 p.a. (under review). Further details and application forms from the Academic Registrar, University of Warwick, Coventry CV4 7AL quoting Ref. No. 35/3A/79. Closing date for receipt of applications May 4, 1979. 367(A)

UNIVERSITY OF GLASGOW CHEMISTRY DEPARTMENT (GC-MS UNIT)

An immediate vacancy exists for a

POSTDOCTORAL RESEARCH APPOINTMENT

tenable for one year, for a project on the analytical and structural characterisation of hydroxysterols by GC-MS and ancillary techniques. Candidates should be steroid chemists, or others familiar with modern liquid-phase and gas-phase methods suitable for the study of microgram amounts of compounds in biological samples of complex composition. Experience of open-tubular glass columns in GLC or GC-MS would be especially valuable. There is a possibility of an overseas visit during tenure of the post. Equipment includes LKB9000 and DuPont 21-490F (CI/EI) instruments, either of which can be used on-line to VG20 Data System. Starting salary in the range £3,634 to £4,133 of the salary scales for Research and Analogous Staff (1A), with U.S.S. benefits.

Applications, naming two referees, should be sent, preferably by April 17, 1979, to Professor C. J. W. Brooks, Chemistry Department, University of Glasgow, Glasgow G12 8QQ, from whom further details can be obtained.

In reply please quote Ref. No. 4413M. 286(A)

ST GEORGE'S HOSPITAL MEDICAL SCHOOL (University of London)

POSTDOCTORAL RESEARCH ASSISTANT

required in the Biochemistry Department for a three-year project to establish fusion hybrids of plasma cells producing antibodies against disease causing protozoa. Previous experience in cell culture and biochemistry or immunology desirable. Salary in the range £3,883 to £4,882 (under review) plus £502 per annum London allowance. Application forms and further particulars available from the Establishment Officer, St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE. Closing date April 30. 343(A)

DIRECTOR, NATIONAL MUSEUM OF NATURAL HISTORY Smithsonian Institution

Applications are being accepted until June 1, 1979 for the position of Director, National Museum of Natural History, Smithsonian Institution, Washington, D.C. Salary is to be \$47,500.

For further information, including copy of the official position announcement, contact: Smithsonian Institution; The Search Committee, Office of Personnel Administration, Box 2500; 900 Jefferson Drive, S.W.; Washington, D.C. 20560.

Applicants should submit Standard Form 171 to the above address.

The Smithsonian Institution is an equal opportunity employer. W39(A)

EAST MALLING RESEARCH STATION POMOLOGY DEPARTMENT

A CROP PHYSIOLOGIST to join, in a support capacity, a team working on root physiology and on irrigation and other methods of reducing tree water stress.

Minimum qualifications needed are an ordinary degree, H.N.C. or equivalent in Botany/Agricultural Science/Horticultural Science.

Appointment in Scientific Officer grade £2,839 to £4,415 starting salary according to qualifications and experience. Non-contributory superannuation.

Details and application form from Assistant to the Secretary, East Malling Research Station, East Malling, Maidstone, Kent. 323(A)

UNIVERSITY OF ASTON IN BIRMINGHAM DEPARTMENT OF PHARMACY SENIOR LECTURESHIP IN PHARMACEUTICS

Applications are invited for the above post. The person appointed will be expected to undertake administrative responsibility for teaching and research in Pharmaceutics. Personal academic interests should be compatible with the existing work of the Pharmaceutics Section, which includes biopharmaceutics, pharmacokinetics, stability and technology. Research expertise relevant to the pharmaceutical industry would be an advantage.

SALARY SCALE: £7,506 to £9,263 per annum (under review). Appointments are normally made to the first point of the scale.

Application forms and further details may be obtained from the Staff Officer (quoting REF. NO. 352/6), University of Aston in Birmingham, Gosta Green, Birmingham B4 7ET (Tel. 021-359 3611, Ext. 201) and applications should be returned not later than April 30, 1979. 314(A)

UNIVERSITY OF NEWCASTLE UPON TYNE POSTDOCTORAL RESEARCH ASSOCIATE IN BIOCHEMISTRY

A postdoctoral research associate is required to join a group working on the isolation and characterisation of monocyte-specific antigens, with techniques including monoclonal antibodies. The project is funded for three years by the Wellcome Trust and involves collaboration between the departments of Pathology and Biochemistry. Experience in membrane biochemistry and/or immunology would be desirable.

Enquiries and applications are invited from persons possessing or expecting to possess by summer 1979 a Ph.D. and should be addressed to Professor R. H. Pain, Department of Biochemistry, Ridley Building, The University, Newcastle upon Tyne, NE1 7RU. Tel. 0632-28511. 318(A)

UNIVERSITY OF LIVERPOOL DEPARTMENT OF ORGANIC CHEMISTRY

Applications are invited for a number of posts of Demonstrator/Senior Demonstrator in the Department of Organic Chemistry. Successful candidates will be expected to supervise practical classes, undertake tutorial work, and carry out research in collaboration with a research group in the Department.

Initial salary within the range £3,384 to £4,882 per annum.

Applications, together with the names of three referees, should be received not later than June 30, 1979 by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/546/N. 365(A)

NEW ZEALAND UNIVERSITY OF CANTERBURY Christchurch

LECTURER IN GEOLOGY (ENGINEERING GEOLOGY)

Applications are invited for the above-mentioned position. Applicants should be capable of teaching courses to both Civil Engineering and Geology undergraduate students, to give assistance in postgraduate work and to undertake research.

Applications close on June 30, 1979. The salary for Lecturers is on a scale from NZ\$11,894 to NZ\$14,615 per annum.

Further particulars and Conditions of Appointment may be obtained from the Association of Commonwealth Universities (Apts.), 36 Gordon Square, London WC1H 0PF. 348(A)

QUEEN ELIZABETH COLLEGE Kensington (University of London) LECTURESHIP

IN MANAGEMENT STUDIES

Applications are invited for the post of Lecturer in Management Studies to join a developing group within the Department of Food Science. Applicants will be expected to have an appropriate academic background with an original discipline in areas such as Economic Geography, Operational Research, Applied Statistics or Applied Economics. The successful applicant will be required to teach courses in the general curriculum of management studies to students following inter-disciplinary degrees in the natural sciences and management. Outside contacts will be encouraged. Industrial research and other relevant experience would be an advantage, and placing on the salary scale will reflect both qualifications and experience; the current scale (under review) is £3,905 to £7,754 per annum plus £502 per annum London Allowance.

Application forms and further particulars are available from the College Secretary, Queen Elizabeth College, Campden Hill Road, London W8 7AH. Tel: 01-937 5411, ext. 209. Closing date: May 4, 1979. 307(A)

UNIVERSITY OF LONDON KING'S COLLEGE

LECTURESHIP IN GEOLOGY

Applications are invited for a LECTURESHIP in Geology. Applicants should have a good honours degree and experience in structural geology; an interest in engineering geology desirable. Field teaching ability is essential.

Current salary scale £3,883 to £7,754 plus £450 per annum London Allowance (both under review). The starting salary will be at an appropriate point on the scale. Universities Superannuation Scheme contributions would be payable.

Further information about the post and Department and application form may be obtained from the Assistant Registrar, King's College London Strand, London WC2R 2LS, to whom applications, in triplicate, should be sent, together with the names of two referees, to reach him by April 26, 1979, quoting reference No. 191669/N 309(A)

UNIVERSITY OF BRISTOL SCHOOL OF CHEMISTRY DEPARTMENT OF PHYSICAL CHEMISTRY

Applications are invited for a

LECTURESHIP IN PHYSICAL CHEMISTRY

tenable from October 1, 1979. Initial salary in the range £3,883 to £6,311 per annum on a scale rising to £7,754 (under review). The successful candidate will be expected to take a full part in laboratory supervision lecturing and tutoring; to engage in research and to participate in the administration of the Department.

Suitably qualified candidates should submit applications, together with the names of three referees, by April 30, 1979, to the Registrar, University of Bristol, Senate House, Bristol BS1 1TH, from whom further particulars may be obtained. Please quote reference EB. 295(A)

UNIVERSITY OF DURHAM DEPARTMENT OF BOTANY

Applications are invited from candidates with interests in molecular and microbial genetics for the post of

LECTURER IN GENETICS

tenable from October 1, 1979. Experience in recombinant DNA technology preferred.

Salary of the scale £3,883 to £7,754 (under review) plus superannuation.

Applications (3 copies) naming three referees should be sent by May 1, 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 1LE (from whom further particulars may be obtained). 218(A)

**UNIVERSITY OF ZURICH
SWITZERLAND
DEPARTMENT OF ZOOLOGY
POSTDOCTORAL
OR SENIOR
RESEARCH ASSISTANT**

Applications are invited for a position to work on a project concerned with the development of muscle in *Drosophila*. Good training in electron microscopy would be preferred.

The appointment is for a period of two years, with the possibility of extension, and could commence as soon as possible. The salary would range from Sfr.27,000 to Sfr.47,000 according to experience.

Applications, in the form of a curriculum vitae, list of publications, names and addresses of two referees, should be sent to Prof. I. Deak, Zoologisches Institut der Universität Zurich, Winterthurerstrasse 190, 8057 Zurich, Switzerland. W33(A)

**BLOOD GROUP REFERENCE
LABORATORY
SCIENTIFIC OFFICER**

A graduate is required for research and development related to the production of antiglobulin reagents for use in blood transfusion laboratories. Some experience in immunochimistry, protein purification or radioimmunoassay desirable, but not essential.

Applications in writing with details of experience and the names of two referees to Miss K. Lomas, Blood Group Reference Laboratory, Gatliff Road, off Ebury Bridge Road, London SW1W 8QJ. 354(A)

**HOUGHTON POULTRY
RESEARCH STATION
LIAISON OFFICER**

Applications are invited for the post of Liaison Officer, the duties of which include liaison with, and an information service for, the poultry industry, veterinary profession, Agricultural Research Council and Ministry, the Press, journals and educational organisations, and the preparation of publications and exhibits.

Applicants should possess a degree, HNC or equivalent in a science subject, with at least 5 years' relevant experience. Experience in public relations and editorial work would be an advantage.

Salary in Higher Scientific Officer grade (£4,101 by 8 to £5,448).

Further particulars from the Secretary, Houghton Poultry Research Station, Houghton, Huntingdon, Cambs PE17 2DA. Closing date for applications: May 11, 1979. 311(A)

**ST GEORGE'S HOSPITAL
MEDICAL SCHOOL
(University of London)
LECTURER IN
IMMUNOLOGY**

The post, which is in an expanding Immunology Unit, is suitable for candidates with a background in immunochimistry or membrane chemistry and perhaps cell culture. The person appointed would be expected to devote a substantial amount of time to research in the first three years and would be well provided with research expenses. Salary in the range £3,975 to £8,250 (under review) plus £502 per annum London allowance. Further particulars available from the Establishment Officer, St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE, to whom applications, with the names of two referees, should be sent to arrive by April 30, 1979. 340(A)

**UNIVERSITY OF
MARYLAND
Baltimore County (U.M.B.C.)
POSTDOCTORAL,
BIOCHEMISTRY**

Available summer, 1979. Research in isolation and characterisation of nucleic acid helix-destabilising (unwinding) proteins; chemical modification, physical, genetic, and immunological studies on these proteins, cationic metal and dye interactions with nucleic acids and polysaccharides. Metro. Baltimore-Washington, D.C. location. Send resumé and three letters of recommendation to Dr Richard L. Karpel, Department of Chemistry, University of Maryland Baltimore County, Catonsville, MD 21228. Equal opportunity/affirmative action employer. W38(A)

**UNIVERSITY OF
LEICESTER
DEPARTMENT OF GENETICS
Applications are invited for a
POSTDOCTORAL
RESEARCH ASSOCIATE**

to work on an M.R.C.-supported project on the mechanism of action of penicillin and the use of this antibiotic to the processes of cell division and shape determination in *Escherichia coli*.

The position is tenable until October 1981 on the range for Research Associates, £3,883 to £6,555. Applications, including the names of two referees, should be sent to Dr Brian G. Spratt at the Department of Genetics, University of Leicester, Leicester LE1 7RH. 296(A)

**MEDICAL RESEARCH
COUNCIL
DEVELOPMENTAL
NEUROBIOLOGY UNIT
INSTITUTE OF NEUROLOGY**

Applications are invited from young postdoctoral morphologists to participate in a programme to study effects of metabolic factors on brain development. Research experience in quantitative morphological method, light and electronmicroscopic autoradiographic, and immunohistochemical techniques will be of advantage.

The appointment will be for one year in the first instance with the possibility of extension for a further two years. Salary will be at the appropriate point on the M.R.C. scale for non-clinical scientific staff.

Applicants should send a Curriculum Vitae giving full details of qualifications and experience, and the names of two referees to Dr R. Balazs, M.R.C. Developmental Neurobiology Unit, Institute of Neurology, 33 John's Mews, London WC1N 2NS. 336(A)

FELLOWSHIPS

**UNIVERSITY OF
CAMBRIDGE
DEPARTMENT OF
ENGINEERING
THE PYE FOUNDATION
RESEARCH FELLOWSHIP IN
TELECOMMUNICATIONS**

Applications for the Fellowship are invited from established postdoctoral research workers to study techniques for the bandwidth compression of speech signals. The Fellowship is tenable from June 1, 1979 for three years, at a salary in the range £4,631 to £6,080 (under review) plus superannuation.

Further particulars may be obtained from the Secretary, Faculty of Engineering, Trumpington Street, Cambridge CB2 1PZ, to whom applications, including a brief curriculum vitae, and the names of two referees, should be sent by April 27, 1979. 360(E)

**THE UNIVERSITY
OF LEEDS
PROCTER DEPARTMENT
OF FOOD SCIENCE
PROCTER
RESEARCH FELLOWSHIP**

Applications are invited for a temporary post of POSTDOCTORAL RESEARCH FELLOW

to study the physics of gelation of water-soluble macromolecules such as gelatin. The project will involve experimental techniques of laser light-scattering and rheological measurement. Applicants should have (or expect to have by October 1979) a Ph.D. in physical chemistry, chemical physics or polymer physics. Previous light-scattering experience would be an advantage. The successful applicant will work in association with Dr. E. Dickinson and Dr. G. Stainby of the Procter Department of Food Science. The appointment will be made for a fixed term of one year. At the end of that period a further fixed term contract for a period of two years may be available. Salary in the range £3,883 to £4,382 on the 1A scale for Research and Analogous Staff (£3,883 to £6,555) (under review), according to age, qualifications and experience.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 72/4/D. Closing date for applications May 21, 1979. 300(E)

**UNIVERSITY OF
EDINBURGH
DEPARTMENT OF
BIOCHEMISTRY
POSTDOCTORAL
RESEARCH
FELLOWSHIP**

Applications are invited for this post to work on the mode of action and uptake of the drug Suramin in *Trypanosoma brucei* and the cause of resistance to that drug.

Salary range £3,883 to £4,382 (plus superannuation). The post, financed by the World Health Organisation's Special Programme for Research and Training in Tropical Diseases, will be for one year initially with possible extension for a further two years.

Applications with curriculum vitae and the names of two referees should be sent to Dr I. B. R. Bowman, Department of Biochemistry, University of Edinburgh Medical School, Teviot Place, Edinburgh EH8 9AG, by April 23, 1979. Please quote Reference 5017. 350(E)

**UNIVERSITY OF
BIRMINGHAM
DEPARTMENT OF
PLANT BIOLOGY
POSTDOCTORAL
FELLOWSHIP**

Applications are invited for an Agricultural Research Council Postdoctoral Research Fellowship, tenable for three years, for work with Dr G. G. Henshaw on plant regeneration from potato tissue cultures. Salary in the range £3,883 to £6,555 (under review), plus superannuation. Maximum starting salary will be £4,382.

Applications including a curriculum vitae and the names and addresses of three referees should be sent to Assistant Registrar, Science and Engineering Registry, P.O. Box 363, Birmingham B15 2TT by Friday, April 20, 1979. Please quote ref: NK7. 337(E)

**HOWE
SENIOR
RESEARCH FELLOWSHIP**

Applications are invited by the Council of the Royal Society for the Howe Senior Research Fellowship, established from the Mr and Mrs R. L. Howe Bequest for the promotion and encouragement of scientific research. On this occasion applications are restricted to those working in the fields of fundamental or applied biological sciences. The appointment will be tenable in any appropriate university department or research institution in the United Kingdom approved by the Council of the Royal Society. Candidates, who must be citizens of the United Kingdom or the Commonwealth, must supply the usual personal details and give two referees. Testimonials will not be considered. The subject of the proposed research, and where it would be done, together with the name of the head of the department, whose consent should first be obtained, must be stated.

The appointment, which will be subject to the Society's general regulations governing research appointments, will be tenable for five years from October 1, 1979 (or another date to be arranged) and may be renewable for successive five-year periods until the end of the academic year in which the holder becomes 65. Applicants should preferably be under 45 on October 1, 1979. The stipend scale will be £8,031 x £252 to £8,878 x £249 to £9,036 per annum, and the point of entry will be determined by Council. Superannuation benefits will be provided. Some provision for research expenses will be available.

Applications should be made on forms to be obtained from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG, and returned by April 30, 1979. 283(E)

**UNIVERSITY OF
BIRMINGHAM
DEPARTMENT OF
PLANT BIOLOGY
POSTDOCTORAL
FELLOWSHIP**

Applications are invited for a Postdoctoral Research Fellowship supported by the Ministry of Overseas Development which is tenable until December 31, 1979 to work on the storage of cocoa seeds. Salary in the range £3,883 to £6,555 per annum plus superannuation. Starting salary will not exceed £4,382.

Further particulars are available from Assistant Registrar, Science and Engineering, P.O. Box 363, Birmingham B15 2TT to whom applications (three copies) including a curriculum vitae and names and addresses of three referees should be sent by Friday, April 20, 1979. Please quote ref: NK6. 285(E)

ASSISTANTSHIPS

**THE UNIVERSITY OF
SHEFFIELD
DEPARTMENT OF
BOTANY**

Applications are invited from men and women for an

**S.R.C. POSTDOCTORAL
RESEARCH ASSISTANTSHIP**

to study physiological and biochemical aspects of seed dormancy in collaboration with Dr B. C. Jarvis. Tenable for two years from September 1, 1979. Initial salary up to £4,382 a year. Applications, together with the names of two referees, to the Registrar and Secretary, The University, Sheffield S10 2TN, by April 20, 1979. Particulars available on application. Quote ref: R 271/G. 331(F)

ASSISTANTSHIPS—cont.

UNIVERSITY OF DURHAM
DEPARTMENT OF CHEMISTRY

Applications are invited for chemists or chemical physicists for an

S.R.C. POSTDOCTORAL
SENIOR RESEARCH
ASSISTANTSHIP

or sixteen months from as soon as possible, to work in collaboration with Dr J. Yarwood on the interaction and dynamics of hydrogen bonded systems in the liquid phase. These studies which include infrared, far-infrared, Raman and neutron scattering studies are also supported by a N.A.T.O. research grant and would be carried out at Durham, the Technical University, Braunschweig and at A.E.R.E. Harwell. Some experience in one branch of molecular spectroscopy is essential and an interest in the chemical physics of molecular motions and interactions in the liquid phase would be an advantage.

Initial salary £3,883 or £4,133 per annum on National Research Range A plus superannuation.

Applications (three copies) naming three academic referees should be sent by April 18, 1979, to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars can be obtained. 278(F)

UNIVERSITY OF DURHAM
DEPARTMENT OF PHYSICS

Applications are invited for a

POSTDOCTORAL
SENIOR

RESEARCH ASSISTANTSHIP

enable for three years from 1st October, 1979. The successful applicant will participate in a new research project devoted to the theoretical study of low energy molecular collisions.

Initial salary in the range £3,883 to 4,882 (plus superannuation).

Applications (three copies) naming three referees should be sent by April 30, 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. 280(P)

GRADUATE ASSISTANTSHIPS leading to M.Sc. and Ph.D. in Chemical Engineering. Stipend up to \$7,200 plus tuition for qualified candidates. Active and stimulating research program. Write Dr John A. Roth, Department of Chemical Engineering, Vanderbilt University, Nashville, Tennessee 37235. Equal Opportunity Employer. W31(P)

STUDENTSHIPS

AGRICULTURAL
RESEARCH COUNCIL
STUDENTSHIP

Applications are invited for an ARC postgraduate studentship tenable at the Meat Research Institute for research into the viscoelastic properties of semi-solid foodstuffs.

The work will involve a study of the transmission of mechanical pulses through foods and computer analysis of transient stresses generated with an Instron materials tester.

The project is expected to form the basis for a Ph.D. thesis in the University of Bristol and the appointment will commence in October 1979.

Candidates should possess a First or Upper Second Class degree in Physics or a related subject.

Further particulars of the award and allowances together with Application Forms may be obtained from the Personnel Officer, Agricultural Research Council, Meat Research Institute, Langford, Bristol BS18 7DY. 310(F)

UNIVERSITY OF
ST ANDREWS
POSTGRADUATE
STUDENTSHIP IN
BIOCHEMISTRY

Applications are invited for a postgraduate studentship financed by the National Fund for Research into Crippling Diseases. The project will involve biochemical research in relation to a particular inborn error of metabolism. Techniques employed in the project will include tissue culture, protein purification, methods of physico-chemical separation such as isoelectrofocusing, immuno- and electro-phoretic methods, enzymology.

The three-year studentship will commence from October 1979. Candidates should hold, or expect to obtain in 1979, a first or upper second class Honours Degree in Biochemistry.

Applications (preferably type-written) together with the names and addresses of three referees should be sent to Dr R. Griffiths, Department of Biochemistry and Microbiology, University of St Andrews, North Street, St Andrews, Fife, Scotland. 352(F)

UNIVERSITY OF BATH
BIOCHEMISTRY GROUP
SCHOOL OF
BIOLOGICAL SCIENCES
S.R.C. RESEARCH
STUDENTSHIP

Applications are invited for an S.R.C., C.A.S.E. Research Studentship, granted to the above department in collaboration with The Chester Beatty Institute for Cancer Research. It is proposed to investigate the potential anti-tumour activity of a range of newly-synthesised deuterio-analogues of glucose and the successful applicant will have the opportunity to gain experience in a range of cell-culture and also enzymological techniques. Further details may be obtained from Dr R. Harrison at the above address. 335(F)

UNIVERSITY OF
ABERDEEN
DEPARTMENT OF
PHYSIOLOGY

A N.E.R.C. Research Studentship is available to study the tolerance of fish red cells to temperature and pressure (Dr A. G. Macdonald) or the hormonal regulation of phosphate metabolism in fish (Dr C. G. Dacke: C.A.S.E. Studentship with N.E.R.C. Institute of Marine Biochemistry). Further information may be obtained from the Head of the Department of Physiology, University of Aberdeen, Marischal College, Broad Street, Aberdeen AB9 1AS. 346(F)

UNIVERSITY OF
ABERDEEN
DEPARTMENT OF GENETICS
Applications are invited for an
S.R.C.

RESEARCH STUDENTSHIP to support study for a Ph.D. degree. A variety of research topics are available in such areas as mutagenesis, comparative genetics of drug resistance in fungi, DNA replication patterns in related species, genetics of herbicide resistance in plants, human cytogenetics in relation to cancer, genetics of colour perception in man, ecological genetics of animal or plant populations.

Details of academic record and names of two referees should be sent to the Secretary, Department of Genetics, University of Aberdeen, 2 Tillydrone Avenue, Aberdeen, as soon as possible and not later than April 4, 1979. 303(F)

NATURAL ENVIRONMENT
RESEARCH COUNCIL
INSTITUTE OF OCEANOGRAPHIC
SCIENCES (BIDSTON)STUDENTSHIP ON TILT
IN THE SOLID EARTH

Applications are invited for a Studentship in the Earth Tide Section of the Institute of Oceanographic Sciences at Bidston Observatory.

The project is concerned with Earth tidal tilt measurements and the effects of crustal structure, ocean tides and shelf tides on the observed tidal signal and will involve some fieldwork in the Lake District.

Candidates should possess a First or Upper Second Class degree in an appropriate scientific discipline.

The successful applicant will be registered for the degree of Ph.D. of the University of Liverpool of which this Institute is an Affiliated Body.

Further particulars of the project and the award may be obtained from Dr R. J. Edge, Institute of Oceanographic Sciences, Bidston Observatory, Birkenhead, Wirral L69 7RA. 294(F)

UNIVERSITY OF
LEICESTER
DEPARTMENT OF BOTANY
N.E.R.C.

RESEARCH STUDENTSHIP

Applications are invited from graduates, or those expecting to graduate this summer, for a N.E.R.C. Research Studentship. The Studentship is available for one only of the following research projects:

(1) Effect of real and simulated vegetation canopies on the maturation and subsequent germinability of weed seeds.

(Supervisor: Professor H. Smith)

(2) Available genetic resources of turf grasses—C.A.S.E. studentship with the Sports Turf Research Institute.

(Supervisor: Dr C. A. Stace)

The first project will be of interest to a plant physiologist/ecologist whereas the second project would be more suited to a plant taxonomist. All promising candidates will be invited to the Department for informal discussions.

Requests for further information and applications should be addressed to Professor H. Smith, Department of Botany, University of Leicester, Leicester LE1 7RH. 313(F)

COURSES

UNIVERSITY OF
BIRMINGHAM
DEPARTMENT OF
BIOCHEMISTRY
M.Sc. COURSE
IN TOXICOLOGY

This course will be offered for the first time in October 1979; it is of one year's duration and is designed to instruct students in the theoretical and practical aspects of toxicology. The full M.Sc. course consists of five modules, each of about five weeks and includes a research project (12 weeks). Applicants should have an honours degree in Biochemistry, Chemistry, Physiology or Zoology or hold a medical or veterinary qualification of equivalent standing. Students having a degree in Chemistry should have taken a course in Biology.

Post-experience students—Individual modules in the above course may be taken by students on release from their posts. Their experience will be taken into account in assessing their suitability for the course.

Application forms and further details of the course may be obtained from the Assistant Registrar (S), University of Birmingham, P.O. Box 363, Birmingham B15 2TT, quoting reference T2. Applications should be received as soon as possible and in any case not later than June 15, 1979. 304(D)

SYMPOSIUM

FEBS SYMPOSIUM
ON DNA

Liblice, near Prague,

Czechoslovakia

24-29 September 1979

Topics: Recombinant molecules of DNA; DNA-protein interactions; DNA recombinations *in vivo*; DNA repair.

Information from: Drs S. Zadrzil and J. Sponar, Institute of Organic Chemistry and Biochemistry, Czechoslovak Academy of Sciences, Flemingovo nám.2, 166 10 Prague 6, Czechoslovakia.

The closing date for applications is May 15, 1979. 250(M)

AWARDS

UNIVERSITY OF BRISTOL
S.R.C. C.A.S.E. AWARD

"Immiscible displacement and capillary condensation"

A postgraduate studentship is available for study of spontaneous fluid movements in porous media, and associated problems in two-component capillary condensation. The work has fundamental relevance to oil recovery processes, and is jointly supported by the British Petroleum Co., Ltd., in whose Research Centre the appointee will be expected to spend several brief periods. Usual S.R.C. conditions apply. Candidates with (or expecting to obtain) a first or upper second class honours degree in an appropriate subject should apply at once to Dr J. M. Haynes, Department of Physical Chemistry, University of Bristol, Bristol BS8 1TS. 279(N)

CONFERENCES

THE NEW YORK
ACADEMY OF SCIENCES
ANNOUNCEMENT OF
CONFERENCECONFERENCE ON THE
STRUCTURE OF
LIPOPROTEINS
New York City

September 10-12, 1979

The New York Academy of Sciences will sponsor a three-day conference on the STRUCTURE OF LIPOPROTEINS. The conference is co-chaired by Angelo Scarni (University of Chicago) and Frank Landsberger (Rockefeller University). Research on plasma lipoproteins is advancing at a very rapid pace. This conference will focus directly on analyses of the structure of these molecular complexes. Recent observations have shown that plasma lipoproteins have a regulatory role in intracellular lipid metabolism, and that they may also be implicated in the genesis of neurological disorders.

The conference will permit a critical analysis of the progress to date in the field of plasma lipoprotein structure and will alert multi-disciplinary investigators to the advances made in the general area of protein-lipid interactions and other relevant biological systems.

To supplement invited lectures, the organising committee will accept a limited number of suitable poster session presentations. The deadline for the submission of abstracts to be considered for poster presentation is on or about June 1, 1979. The abstract should include the names of the author(s), institution and 100 to 200 word summary of work to be presented in the poster. Send abstracts for poster session and inquiries about details of the programme and registration to:

Conference Director
New York Academy of Sciences

A new approach in tissue culture

PETRIPERM

a novel culture dish with gas permeable membrane as cellular support.

Additional advantages of the PETRIPERM membrane are:

- UV permeable 200 nm
- Suitable for high power light and fluorescence microscopy
- The membrane can be cut for cell cloning, electron microscopy, staining and documentation
- Chemically resistant to acids, bases and organic solvents

PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.

In the intact animal, the pH, and the partial pressure of both oxygen and CO₂ of the cell environment are under total biochemical and physiological control. This state is not even approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. PETRIPERM is the prerequisite for the precise control of pO₂, pCO₂ and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable 25 µm thick membrane.

Heraeus—CO₂-Incubator B 5060 EK/CO₂

We build the incubator with appropriate pCO₂, pH and pO₂ control units

How Britain runs its science

This highly successful chart, which appeared in Nature 28 August 1975 (but is still much requested and much referred to), has now been completely revised and updated to include all major changes in the personnel and administration of British science.

Measuring approximately 2' x 3' and containing black-and-white illustrations of prominent figures, copies of this chart are now available at 75p (UK), US \$1.50 (Rest of World).

Payment may be made in any currency at the prevailing exchange rate. Cheques should be made payable to Macmillan Journals Ltd. Prices include postage and packing.

To order please complete the coupon below, or write, enclosing the correct remittance.

FX-90Q 90MHz Integrated Broadband DQD FT NMR

The FX-90Q brings you total flexibility, high performance and unparalleled ease of operation – and the unique OMNI Probe* design.

*OMNI Probe design

All nuclei (6.5~36MHz) observable, including ^1H and ^{19}F . Full range of exchangeable sample inserts by simple plug-in technique. Big savings on cost and time in preparing separate probes for different sample sizes or nuclei.

- Multi-nuclear observations with a simple plug-in module
- High performance carbon/proton with a dedicated plug-in module
- Higher sensitivity without ghost images and easier to interpret spectra
- Foreground/background operation
- All frequencies selected via light pen control system

Growth rings in dinosaur teeth

MIX AND SPIN PERCOLL™

 **DENSITY
MARKER
BEADS**

NOW AVAILABLE
for calibration of gradients of Percoll

Now centrifugation is simpler,
quicker and gives much greater resolution
than you ever thought was possible.

Self-generating gradients in 30 minutes or less

Isoosmotic throughout the gradient

Non-toxic to cells and viruses

Does not interfere with enzyme assays or quench radioactivity

Low viscosity for rapid isopycnic or rate zonal separations

Suitable for cells, viruses and subcellular particles

THE GREATEST REVOLUTION SINCE THE CENTRIFUGE

Contact your normal supplier today for a free descriptive booklet.

Why is a beautiful
hotel like the Pulitzer
featured in a
magazine like this?

Guess!

Even a scientist needs to relax

The four star Pulitzer is located along one of Amsterdam's most famous canals in the heart of the city. 17 historic buildings were completely restored to their original beauty and combined to house 175 guest rooms all with modern facilities. Graced with beams and natural brick walls, each room reflects a rustic charm not found elsewhere in Amsterdam.

You'll find a cozy bar to relax after a busy day. A restaurant which serves delicious Dutch and French food. And keep in mind that the Pulitzer has private meeting facilities up to 60 persons.

So when you're planning a trip to Amsterdam, remember the Pulitzer.

For additional information and instant free reservations: Call Nicholas Lawson Ltd. London: 01/4917431, telex 23189.

KANAMYCIN ACETYL TRANSFERASE

Available From Stock

Kanamycin 6'-acetyl transferase (KAT) has been used successfully with the Gentamicin E-R A™ kit (PL Cat. No. 9088) for the assay of kanamycin, tobramycin, amikacin (BB-K8) and netilmicin. KAT is a broad-spectrum enzyme which transfers an acetyl group from acetyl-coenzyme A to a wide variety of aminoglycosides.

0844 Kanamycin 6'-Acetyl Transferase (E. coli)

Prep: Solution in buffered 50% glycerol, approx. 20 units per ml.

Activity: Min. 20 units/mg protein. One unit catalyzes the acetylation of 1 nanomole of kanamycin per minute at 30°C, pH 5.7 (Ask for procedure E844)

10 units \$30.00

1115 Kanamycin Sulfate 1 gram \$8.50

Circle No. 10 on Reader Enquiry Card.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; $\exp(a)$ is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note.

(i) only one reference number need be used if the reference is to several papers by identical authors

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

Molecular biology: suffering from shock

THE recent meeting of molecular biologists convened by COGENE, the Committee on Genetic Experimentation of the International Council of Scientific Unions, was an instructive affair—but not in the way the organisers intended. The lesson came in their treatment of the press. First the meeting was open; then it was closed to journalists. Then it was open to three journalists picked by the Association of British Science Writers, but the proceedings were to be 'off the record'. Then at the last moment all restrictions were lifted.

To be fair, the organisers of the meeting—COGENE and the Royal Society—admitted they had made a mistake; they were under pressure, it seemed, from biologists who had had bad experiences with the US press. And the press is certainly no angel. But the meeting's attitude to it was symptomatic of a deeper malaise: that despite the promise of the 'Berg letter' (*Genesis*, someone called it) which launched molecular biology into politics, biologists have failed to grasp the nettle of their relationship to the public. The press, after all, represents all the fears and frustrations of its readers: it is the public writ in 48 point bold caps.

However the molecular biologists—if the COGENE meeting was a guide—now feel that their subject has no right to be in the public arena at all. The Berg letter called for a pause to assess the risks of the recombinant DNA technique, we have had the pause, and the risks are found to be negligible. So why don't the NIH, and GMAG, and the other regulatory agencies just go away? That was the strong mood of the meeting. "We want to achieve re-entry," someone said. But as Sir Frederick Warner, one of the assessors at the Windscale inquiry into nuclear reprocessing, told the meeting, the three great fears have been raised in the public mind: carcinogenesis, mutagenesis, and teratogenesis. The public won't go away. Re-entry into the womb is no longer possible, even if it seems rational.

Paul Berg's two revolutionary impacts on molecular biology—the recombinant DNA technique itself, and (with the other 10) the Berg letter—have left molecular biologists in a state of shock. Within six years they have found an immensely promising research technique; they have entered biotechnology, with undreamt-of profits to be made; and they have entered politics with their perfectly rational whistle-blowing over conjectural risks. All this happened at just the time when a new breed of radical scientists was searching for something to cut its teeth on, and when the regulation of science and technology was becoming fashionable among governments. So no wonder the biologists are reeling.

No doubt the organisers of the COGENE meeting intended that it should come to terms with this new climate.

But it only reacted to it. Four major issues facing molecular biology were either not addressed or left unresolved. First, what really are the arguments that the risks are negligible? Although there were interesting talks—such as that of Walter Bodmer on species barriers—which were relevant to the question, there was no scientific *debate* of the matter. Where were the critics—and there are scientific critics, with genuine arguments—to bring matters to a head? To the outside observer the view that risks are negligible went through on the nod. If the biologists are to face the public they must do better than communicate a mood; they must construct arguments that are for more than internal consumption. To do that they must embrace their heretics, not spit at them.

Second, there was not a minute of discussion of the new procedure for risk assessment devised by Sidney Brenner and recently adopted by Britain's Genetic Manipulation Advisory Group. Confounding its critics who complain that biological knowledge is to patery for it to work, this method is already in use in GMAG, and has resulted in the down-grading of a number of experiments. If it is false, it should be exposed; if it is correct, being simple and logical it could be the basis of communicating the biologists' new mood to the public.

Third, if there was no scientific debate, neither was there political debate, despite the fact that it is clear that the biologists' re-entry must be a political one. The most moderate voices, such as that of Mark Richmond, showing sensitivity to politics and public opinion, sounded radical against the growls of the rednecks, and were submerged.

Fourth and last, the role of molecular biology in technology, where recombinant DNA is the microprocessor chip of the pharmaceutical industry, was dealt with only at the level of bioengineering and gee-whizzery. And yet here is a technique which has already generated a new social world for the biologist, who is becoming suspicious of his colleague's motives (does he want my enzyme for profit or for science?) and hungry for a new kind of success. Is that not a significant development? Why was it not a subject for debate? Further, what impact will this technique have on medicine and agriculture? Should it be left to the few secretive new firms that are engaged on it, or do we have a chance to create a humane and democratic technology? These questions were ignored.

Molecular biologists are firmly in politics now, and it is totally irrational to ignore the fact. Nuclear physicists should envy them: for the physicists generated their technology first, became committed to it, and burnt their political fingers later. The biologists have the opportunity to learn their politics first, and grow with it. They should not miss the opportunity. □

California calls for nuclear shutdown

David Dickson reports from California on reactions to the accident at the Harrisburg nuclear power plant

THREE years ago, the citizens of California voted by a two to one majority against any curb on the development of nuclear power. Last week, following the accident at the Three Mile Island nuclear power plant in Harrisburg, Pennsylvania, which took over a week to bring under control, and resulted in the discharge of radioactive isotopes into the local environment, an informal survey by a San Francisco newspaper based on telephone calls from readers revealed a 56% majority in favour of shutting down all nuclear power plants.

No one pretends that the California figures are a true reflection of attitudes across the US. California's maverick tradition on "lifestyle" issues, together with a high incidence of sunshine that makes it relatively well placed with respect to alternative sources of energy, both tend to inflate public opposition to nuclear power.

However, the shift in attitude, to judge from press reports, does reflect a public mood. Governor Jerry Brown, his presidential ambitions not far below the surface, has argued with both the Nuclear Regulatory Commission and the local utility company for a temporary shutdown of the Rancho Seco power plant in California (which like the Harrisburg plant was designed by the engineering firm Babcock and Wilcox). And even some of those who had previously been staunch supporters of the nuclear industry are voicing concern that perhaps the Harrisburg incident indicates that not all is as it should—or had been made out—to be.

Defenders of the industry are using the fact that the amount of radiation released to the atmosphere has been minimal, and well below levels claimed to have a harmful effect on humans, to argue that the industry had shown that its safety precautions worked. "Reactors are designed to survive the failure of instruments, which is why they have back up systems," said Dr Edward Teller, so-called "father" of the hydrogen bomb, and now with Stanford University's Hoover Institution. "The worst-case estimate is that some people were exposed to about 50 millirems. Airline hostesses get that in about 50 hours of flight, which they can probably accumulate in about three weeks," Dr Teller said.

But Professor Joseph Rotblat, Emeritus Professor of Physics at St. Bartholomew's Hospital, London University, points out that if the official figure of 25 millirem per hour within a five-mile radius was sustained for the first week of the accident, the 24,000

inhabitants within the five-mile radius could have received a total of 5 rems. This exceeds the maximum allowable dosage for radiation workers of 3 rems in any 13-week period and is ten times the permissible value for the population at large. Official estimates attribute one cancer case per 10,000 population per rem, but, says Rotblat, "this estimate is perhaps a factor of ten too small", which would imply an additional 120 cancer cases because of the accident.

If the incident did little to shake the support of firm supporters of nuclear power, neither did it come as much surprised to nuclear critics. "This is just the type of thing that we have been warning people would happen," said Mr Bob Judd, director of California's Office of Appropriate Technology in Sacramento.

"But we've put a million dollars into Meltdown at Rancho Seco!"

Where there has been a perceptible shift, however, is in those who have yet to come down firmly on one side or another. In the California state legislature, a number of politicians who still support the development of nuclear energy voiced concern at the implications of Harrisburg—for example, at the fact that the formation of the hydrogen bubble which formed at the top of the containment vessel, and gave the greatest source of concern, had never entered anyone's calculations as a potential event—and supported Governor Brown's call for a temporary closure of Rancho Seco.

Similarly on university campuses some of those previously sympathetic to the anti-nuclear movement, but sceptical of its apparent "anti-technology" stance, admitted that the Harrisburg incident had shifted their perspective. "I am beginning to believe that there is something inherently unstable about nuclear power; that unlike other energy sources, the more you develop it, the more you have to develop systems to keep it under control," says Professor Charles Schwarz, professor of physics at the University of California at Berkeley.

The incident hung like a black cloud

over the proceedings of a San Francisco conference on "science, technology and the human prospect" which had been organised jointly by the Electric Power Research Institute and the Thomas Alva Edison Foundation as part of a year-long commemoration of the invention of the electric light one hundred years ago.

The opening day of the conference coincided with Governor Brown's call for the closing of Rancho Seco. Dr Chauncey Starr, Vice-President of EPRI, admitted at a press conference that he would have liked to discuss some of the broader issues being raised by the conference, billed as "a unique opportunity to explore the impact of science and technology on society's development". But all the questions, inevitably, turned on Harrisburg.

"Give us the facts. We want facts, not opinions," demanded one journalist, as Dr Starr explained that at present the precise sequence of events within the reactor that had led to the accident was unknown, but assured people that the levels of radiation to which the local community had been exposed were "so low that they were below any physiological danger to anyone, including pregnant women."

The accident did not change the long-term picture, he said. The initiating circumstances—the apparent failure of a pump circulating the cooling water—was not uncommon, and the statistical probability of the accident fell within the range that had been predicted for the nuclear power programme over 400 reactor years of operation. "Risk analysis is not going to be changed in any particular way by this," Dr Starr said.

"Although something happened in this plant that we do not yet fully understand, no one has been hurt, and there is no public danger that any of us can see. I do not think that shutting down nuclear power plants is a way to increase public confidence. We will continue to do our best to get the public to understand that there are sufficient assets to nuclear power compared to other energy sources, and that the health risks remain very much less. Remember that even steam boilers blow up."

Back in the less charged atmosphere of the conference, speakers talked in general terms about the need to maintain confidence, that society could learn to control the technology that it had developed, and claimed that the Harrisburg incident should reinforce—rather than dent—this confidence (though most were reluctant to get into a detailed discussion of the incident itself). □

President Carter is briefed in the control room at Three Mile Island by Harold Denton of the NRC (left).

Harrisburg: counting the cost

At Harrisburg, the accident still poses enormous clean-up problems. The radiation level inside the reactor containment dome reached 30,000 rems per hour, and officials face the task of cleaning up 250,000 gallons of radioactive water from inside the reactor vessel itself. "We are looking at plans to bring the reactor to a cold shutdown without an increased leakage from the plant" said Harold Denton, Director of Reactor Regulation of the Nuclear Regulatory Commission (NRC). But Senator Morris Udall said it would be months before any clean-up could begin, "if, indeed, a clean-up is possible".

In the meantime, there have been press reports blaming the Metropolitan Edison Company for violating Federal regulations for reactor operation. The *International Herald Tribune* cites detailed NRC reports that valves controlling the emergency water supply to the reactor's cooling system had been closed for two weeks for routine maintenance. Mr Darrell Eisenhut, an engineer for the NRC, told a press conference that in addition the analyses showed that the main cooling system had been turned off at the wrong time and that four auxiliary pumps were disengaged in violation of Commission regulations. These faults combined to cause 60,000 gallons of radioactive water to flood the reactor chamber to a depth of eight feet. The zirconium in the reactor fuel cladding then combined with the water to release hydrogen gas which created a large 1,000 cubic feet bubble at the top of the vessel, causing the fuel rods to overheat and rupture releasing fission products into the water.

In a letter to *The Guardian* in London, Sir Martin Ryle of the Cavendish Laboratory in Cambridge said that the deficiencies of the emergency core cooling system of

the Harrisburg family of pressurised water reactors (PWRs) had "been known publicly for five years and by the US Atomic Energy Commission for considerably longer". According to Ryle, the system consists of four separate methods of cooling and relies on correct working of monitored temperature, pressure and waterlevel and the correct sequencing of the various pumps and valves. "It is an excessively complicated system that has never been tested except for 'tests' by computer simulation", said Ryle. He added that the highly dangerous hydrogen bubble should have been predicted as a matter of "A-level textbook knowledge" or failing that as the result of an "afternoon's experiment".

In the financial world, the accident touched off heavy sales of nuclear power related stocks. The US stock market as a whole suffered a broad decline which was attributed to investors worrying over the implications of the accident for the US energy situation. However, stock in Columbia Pictures, owners of *The China Syndrome*, a film about a nuclear meltdown "somewhere in Pennsylvania", rose as its box office takings reached a new high. An anti-nuclear group in South Carolina reported that their phones had been busy 16 hours a day. "People call up and say I can't believe it. I saw the movie and then came home and saw the same thing on the 11 o'clock news."

Daniel Ford, executive director of the Union of Concerned Scientists, called on President Carter "to seek immediate removal" of Dr Joseph Hendrie as chairman of the NRC. Ford was reported as saying that Hendrie had participated in a "far reaching cover-up of critical nuclear safety difficulties".

Joe Schwartz

Joe Schwartz monitors world wide reactions

'We all live in Pennsylvania..'

IN THE UK, the Secretary of State for Energy, Tony Benn, said that before the accident he had faced continuous pressure to "go American" and replace Britain's gas cooled reactors with American PWRs similar to the Harrisburg design. Pressure came from advisers, civil servants, and the nuclear industry itself, but he rejected the plan. Benn said the Harrisburg accident proved that "energy decisions must be kept under democratic control of Parliament". Prime Minister James Callaghan told Parliament: "We have been very wise in concentrating on a safer type of reactor." One of the three firms competing for the order of Britain's first PWR is Babcock and Wilcox; the others are the West German company Kraft Werke Union and a consortium which includes Rolls Royce and Northern Engineering.

France and West Germany, the two most committed nuclear nations in Europe, sent scientific teams to Harrisburg to inspect the accident. Two West German experts reported that the reactor was closer to a core meltdown than was publicly admitted.

The French Government announced its intention to proceed as usual with nuclear development, but the Opposition and the trade unions have called for a re-examination. Francois Mitterand, leader of the Socialist Party, accused the government of secrecy and high handedness in pushing through its power programme. The Socialist minority in parliament called for a halt to France's plan to build nine additional PWRs similar to the Harrisburg reactor in the next five years.

Prime Minister Raymond Barre told the European Press Club: "We must multiply our security measures but France cannot renounce nuclear energy". Minister of Industry Andre Giraud said: "An accident of this type has been taken into account in the design of French nuclear plants."

Le Monde reported numerous criticisms of the Government's stance. The Committee of Interregional Ecological Movements (CIME) demanded an immediate halt to the French nuclear programme because of the danger to urban centres. A Harrisburg-type accident, CIME said, would contaminate 300,000 people around the Fessenheim reactor (Mulhouse), 100,000 around Flamanville (Cherbourg) and 500,000 around Pellerin (Nantes).

The most dramatic action in France

was at the Mediterranean naval base near Toulon with the bombing of several million dollars worth of reactor equipment intended for export to Iraq, West Germany and Belgium. Responsibility was claimed by a group of militant ecologists in a call to *Le Monde*. The caller said "We have succeeded in neutralising machines dangerous to human life." However, French officials are reported as believing that the bombing may have been an Israeli action directed primarily against the Iraqi reactor programme.

In West Germany, 35,000 demonstrators at the Gorleben hearing into nuclear reprocessing plans in Lower Saxony chanted, "we all live in Pennsylvania." Inside the hearings, a French scientist, Yves Lenoir of the mining academy of Fontainebleau, walked out of the meeting of 60 international experts saying that the hearings were a sham and had no influence over the decision. Lenoir said that any discussion of safety that did not take into

account the Harrisburg events was academic.

But the Ministry of the Interior in Bonn said that German safety standards were high compared with international standards but they would be "toughened up" drastically. "Utilities and the nuclear industry will have no chance to ease safety precautions," a spokesman said.

In Sweden the Opposition party demanded that the Ringhals Two plant near Goteberg—a PWR similar to Harrisburg—should be closed for inspection; and Premier Ola Ullsten announced a national referendum on the country's nuclear programme. Danish politicians urged greater debate before their country took a decision to build nuclear reactors, and in Belgium the mayor of the town of Huy, 40 miles south-east of Brussels, ordered the closing of the 870 MW reactor, Tihange 1, saying that the Harrisburg accident had shown the town's emergency preparations to be inadequate.

In Japan, Premier Masayoshi Ohira said there would be no change in Japan's programme which currently has 19 reactors producing 11% of the country's energy. But 100 demonstrators staged a sit-in at the Ministry of International Trade and Industry calling for a thorough inspection of all Japan's nuclear power plants. The ministry itself was holding an emergency meeting with officials from 15 areas to discuss nuclear safety measures.

In Eastern Europe, comment on Harrisburg was limited. Soviet television devoted 15 minutes to the event on 2 April saying, "the accident has provoked a profound anxiety and continues to alarm the American people. A particular indignation has been aroused by the fact that the energy monopolies, in searching for profits, do not take the necessary measures in order to assure the safe functioning of nuclear power stations." □

Guidelines should go, DNA meeting concludes

Eleanor Lawrence reports on a meeting where biologists scoured themselves for going public on conjectural risks

LAST week in the village of Wye, deep in the Kent countryside, an audience predominantly composed of molecular biologists overwhelmingly reiterated the now widely-held view that recombinant DNA research poses no special risks.

The meeting was convened by the Royal Society and COGENE, the Committee on Genetic Experimentation of the International Council of Scientific Unions, to discuss the status of recombinant DNA work and the guidelines controlling it.

Essentially most scientists working in the field now believe that the original fears were based on bad scientific judgment, and that recombinant DNA experiments at the very worst can pose no more hazard than that of working with the most dangerous organism involved in the experiment. Therefore, they argue, regulations for recombinant DNA research are unwarranted and should be abolished. The inconsistency inevitable in guidelines designed to guard against conjectural hazards and the bureaucracy involved in their implementation pose a threat to the freedom of scientific enquiry.

The scientific basis for the change of heart appears to rest first on advice from experts in infectious diseases that it is virtually impossible to convert the laboratory strain of the common gut organism *E. coli* into an epidemic pathogen by the random insertion of a block of foreign genes.

The fear that the insertion of animal virus genes into *E. coli* would result

in a new route for the virus to bypass normal host defences is now also held to be groundless. The current conventional wisdom is that work with cloned viral DNA poses, if anything, even less risk than work with the virus itself, and that cloned viral DNA fragments offer the safest way to study the molecular biology of the most lethal viruses such as Lassa or smallpox.

Joe Sambrook of Cold Spring Harbor Laboratory observed that had Professor Bedson been working in Birmingham with cloned smallpox sequences rather than the complete virus, both he and Janet Parker would be alive today. (The World Health Organisation is indeed considering the possibility that cloned fragments of smallpox DNA might be the safest way of conserving the smallpox genome for posterity.) Although little direct evidence addressing this question was available in 1977—when the Ascot Workshop's recommendation of such views to the NIH was influential in gaining considerable relaxation of guidelines for work with animal viruses—experimental support in the case of certain DNA viruses, at least, has recently been obtained from the NIH 'worst case' polyoma virus experiment (see box).

Participants in the debate also marshal evolutionary arguments, such as the growing appreciation that genetic exchange occurs across wide species barriers in microorganisms, as general ammunition. But it is not clear that

these arguments necessarily address the particular point that still worries those who see the need for guidelines. They ask to be assured that the specific product of any given recombinant DNA experiment is not going to be hazardous to those who may be exposed to it, either in the laboratory, or in the general environment.

Among those who call for the end of regulation a more subjective attitude is that expressed most forcibly by J. D. Watson of Cold Spring Harbor. Watson now attributes the call for the moratorium as mixture of fears over research with tumour viruses themselves and an attack of mild liberal guilt, and considers that he and this fellow signatories displayed a complete lack of scientific judgment. "We were jackasses," he told the conference. "It was a decision I regret; one that I am intellectually ashamed of." Watson adopted this position soon after the original 'Berg letter' was written.

Another signatory, Stanley Cohen of Stanford University, also felt the group's original action was irresponsible on scientific grounds, as well as politically naive. It was based simply on a "lack of certainty there was no risk" and was therefore an "irresponsible scientific argument."

The third signatory present, Norton Zinder, holds a somewhat different view. Although he now thinks their original fears to be groundless, in the circumstances as they saw them at the time there was no other action that could be taken.

Given that they now largely have the support of their scientific colleagues on

guideline committees, the problem now facing those who wish to get rid of public guidelines was neatly summed up by Mark Richmond, a member of the UK Genetic Manipulation Advisory Group. Publication of the Berg letter, he pointed out, was in effect a political act even though there had been no political intention. But through this political act the subject has lost its innocence, and it is now going to be hard for the scientists involved to regain a position in which their views can be regarded as objective.

"How are you going to reassure the public that you're not arguing from self-interest", said Richmond, "but that you are now arguing objectively—particularly when, looked at from the outside, you seem to make enormous quantum jumps between what you require for conditions at one time and what you required for the same experiments a couple of years ago".

R. Pritchard, Professor of Biochemistry at Leicester and a well-known opponent of the UK GMAG reiterated his opinion that the effect of the Berg letter was largely due to the eminent names appended to it, and that its message could only be countermanded by the authors themselves. They should state publicly and unequivocally what they now believe, he said, to the loudest round of applause of the meeting.

Not all the participants, however, judged the display of public recantation before the Inquisition to be warranted. In the perception of a historian of science, Charles Weiner of MIT, the recombinant DNA debate has not been the wasteful and illborn episode it seems to most of those concerned.

Weiner has followed the tortuous course of the debate from the beginning and has collected in his *Recombinant*

'Worst case' experiments show low risk

THE original fears which led to the call for a moratorium were largely prompted by the prospect that cloning animal viruses, and especially tumour viruses, would provide them with a new or more effective way of overcoming host defences. The first results, reported recently, from the NIH 'polyoma experiment' designed to test this proposition were reassuring. Tests of the infectivity of complete copies of polyoma DNA cloned in plasmids or phage lambda showed it to be non-infectious, or much less infectious (by a factor of 10^6) than polyoma virus itself.

One of the NIH experimenters, Dr M. Martin of the National Institute of Allergy and Infectious Diseases, told the Wye conference of results they now have on the tumorigenicity of cloned polyoma DNA. *E. coli* carrying plasmids containing one copy of polyoma DNA produced no tumours when introduced into newborn hamsters; polyoma virus introduced in comparable conditions produces tumours in all animals infected.

The circular recombinant plasmid DNA itself produced a few tumours when given in quantities equivalent to 10^6 times those at which polyoma virus is invariably tumorigenic. As expected from the previous infectivity experiments, bacteriophage lambda-containing dimeric polyoma DNA also caused tumours in a few cases.

The NIH experiment was delayed first by the regulations against the cloning of animal viruses and then by a private legal suit brought against NIH which sought to prevent the experiment. A group of European scientists sponsored by EMBO to undertake similar polyoma infectivity experiments completed initial *in vitro* infectivity tests (which came to essentially the same conclusions as the NIH study) last year under the then less restrictive UK regulations, but have been unable to carry out animal infectivity or tumorigenicity tests because of the lack of any approved facility for such animal experiments in Europe.

In contrast to the US team they were able to obtain dimeric polyoma DNA cloned in plasmids (the NIH scientists could only obtain dimeric polyoma inserts in lambda) which will now be tested for animal infectivity and tumorigenicity at Fort Detrick.

DNA Archive at MIT much of the formal documentation, supplemented by the informal accounts of those involved. Although molecular biologists found the experience of coming face to face with the apprehensions of society a traumatic one, they have, in Weiner's opinion, come through with their science and honour relatively unscathed.

Despite the trauma and despite the

bureaucracy said Weiner, recombinant DNA research flourishes. Has the whole debate and its attendant publicity, he wondered, stimulated rather than repressed the research? But he was concerned at the attitude he now sees amongst younger scientists, to whom the message of the recombinant DNA debate now seems to be "shut up or be shut down".

US regulators countenance abolishment of the guidelines

INDICATIONS that the administrators most closely concerned are sympathetic to the efforts of the US scientific community to disentangle itself from the coils of recombinant DNA guidelines were provided by the statement at the conference from the Director of NIH, Donald Fredrickson.

Fredrickson's decision to go public on the proposed guidelines early in 1976 exposed the scientists to the full force of a public debate. But Fredrickson maintains that this was the only way to release the rising tension and "to prepare to defend whatever actions would be taken, against certain criticism".

The first NIH guidelines were released in June 1976, and greatly relaxed guidelines came into force early this year. In his Wye address, Fredrickson described the latest guide-

lines as a "new set of rules painfully formulated during this unprecedented curtailment of experimentation in biology".

In his view one of the important achievements of the revision was to provide for continuous and orderly evolution of the rules—"even to their eventual elimination when the need passes". Further revisions are due to come into force within the next few weeks, notably the approval of strains of *Bacillus subtilis* and *Saccharomyces cerevisiae* host-vector systems for various levels of containment, a provision hitherto lacking in the NIH guidelines.

H. DeWitt Stetten, former Chairman of the Director's Recombinant DNA Advisory Committee, used his talk to describe his personal route to disenchantment. After battling with the

myriad inconsistencies embodied in the first guidelines he eventually came to the conclusion that they had "got off the track badly" and were doing things that were very wrong—given that the mission of NIH was to support and encourage research.

He decided that the hazards had been overstated as no one could give him any evidence that there was any hazard. He concluded that "we had erected a bastion against a phantom", and that the barriers built to exclude ghosts were composed of scientists' time, effort and money. He has proposed that the guidelines be reduced to one simple rule: "the appropriate conditions of containment for recombinant DNA experiments should be those of the most virulent micro-organism entering into the experiment".

Lower Saxony stalls for time in wake of Harrisburg:

The six-day international hearing on the planned nuclear reprocessing facility at Gorleben in West Germany was very much influenced by the events of Harrisburg. Most of the proponents or "neutral participants" were obviously interested in gaining time. The organisers of the hearings—the state government of Lower Saxony—and the increasingly involved public (the largest anti-nuclear demonstration in Germany with over 100,000 participants took place during the week) were presented with two entrenched and irreconcilable camps. The pro-nuclear lobby insisted that the gigantic project could be realised, and proposed 1994 as a new start-up date for the reprocessing plant. The anti-nuclear lobby maintained that the project was more complicated, dangerous and expensive than simply storing nuclear waste underground. The Lower Saxony government is expected to take its time in assessing the meeting and may defer a decision until after elections for the European Parliament and the state government of neighbouring Schleswig-Holstein. Surprisingly the government granted permission for further trial drilling to a depth of 250m but only outside the area of the salt domes where final storage is planned. The main aim of the drilling is to find out about the surrounding hydrological structure.

From Klaus Höpfner in Hanover

US tries to stop proliferation in Pakistan: The State Department has announced that the US is cutting off development aid to Pakistan amounting to £20m this year and £23m next year in an effort to prevent Pakistan building a uranium enrichment plant. The action was required by a Congressional ruling to deny aid to countries rejecting nuclear inspection or safeguards. US officials became suspicious because Pakistan does not have reactors that can use enriched uranium. According to *The Guardian*, a spokesman from the Pakistani Foreign Ministry in Islamabad "angrily rejected" claims that Pakistan was planning to build an atomic bomb. "Somehow it gives rise to more concern if an Islamic country carries out research into some areas of nuclear technology than if other countries in the world do so" said the spokesman.

US intelligence sources claim that Pakistan has been surreptitiously buying equipment to make a gas centrifuge enrichment facility. The centrifuge was purchased in Holland and high frequency electric power converters were purchased from Emerson Electric in the UK. The UK government stopped the export after it was told about its potential military use.

ESA and NASA agree on joint solar-polar mission: The European Space Agency and the US National Aeronautics and Space Administration have signed a memorandum of understanding for a joint International Solar Polar Mission (ISPM) to be launched in 1983. ESA and NASA will each provide a spacecraft, and ESA will supply software and support personnel to manage the ESA flight operations and data processing at the mission control and computing facility which will be provided by NASA. The two-spacecraft mission is designed to observe the Sun from above and below its polar regions. The spacecraft will be launched simultaneously by the Space Shuttle and will travel in the ecliptic plane out to Jupiter where they will swing around under the influence of Jupiter's gravity to head back towards the Sun on orbits out of the ecliptic plane, one heading towards the Sun's north pole, the other towards the Sun's south pole. The spacecraft will circle the Sun on this polar orbit and then head back to Jupiter. The period from

launch to the second polar passage will be about five years. The mission will also investigate the interplanetary medium during the initial Earth to Jupiter run and the Jovian magnetosphere during the Jupiter fly by.

Comprehensive schools maintain standards in science: Pupils at inner London's non-selective (comprehensive) schools obtained almost the same number of O level and CSE grade 1 passes in biology, chemistry and physics as those from selected intake schools in 1977, and the comprehensive schools achieved these results despite having inferior science facilities and spending less time on the subject. These are the conclusions of a report issued by the Inner London Education Authority science inspectorate. The report expressed concern about the imbalance in facilities, and emphasised that the excellent examination results achieved by dedicated comprehensive school staff should "in no way be taken as an excuse for doing nothing to improve the resources in these schools".

The poorest science facilities were in non-selective mixed and girls schools. According to the report, the main reason for the differences was probably the greater range of subjects taught in comprehensive schools. They had proportionately less resources to spend on science subjects than selective schools since they had to teach subjects such as home economics, design and technology. Selective schools tend to offer only traditional subjects. However improvements are in progress.

Dr John Price, ILEA senior science inspector, said the authority's schools subcommittee had recommended setting up a central task force of 30 science teachers by 1980-81 who will help out in any school where there is a temporary shortage of science staff. The schools subcommittee has also pressed for the urgent review of the staffing and pay points system which causes comprehensive schools to have fewer experienced teachers. Finally, all schools will be given minimum laboratory facilities which will be improved in later years when more money is available.

India prepares for monsoon measurements: India is making major preparations for the forthcoming Monsoon Experiment (MONEX-79) which will enhance understanding of monsoon circulation around the three seas bordering India: the Arabian Sea, the equatorial Indian Ocean, and the Bay of Bengal. Four ships and one plane from India will be supplemented by five Soviet ships and three US planes with further information to be gathered by meteorological balloons and cyclone warning radar stations situated along the Indian coast. Marine weather reports from merchant ships and upper air reports from commercial aircraft will also be analysed.

Three of the Indian ships are expected to be equipped with Navaid sounding systems obtained through the World Meteorological Organisation and the fourth with an Indian-made Omega system to enable them, for the first time, to make systematic recordings of upper winds over the seas around India. Indigenous 3-D scanners will be attached to the 10cm radars at Calcutta and Madras to enhance observational capability, while wind and temperature observations of the stratosphere will be measured by rockets fired from Thumba, Sriharikota and Balasore.

MONEX-79 is a sub-programme of the First Global Garp Experiment (FGGE) of the GARP (Global Atmospheric Research Programme). It will coincide with the launching of FGGE on 1 May and will end in August when the monsoon abates over India. Rs 250 million will be spent on the experiment.

From Dilip M. Salwi in New Delhi

How safe is the fast reactor?

Fast breeder reactors are an essential part of a nuclear future — but in the light of the incident at Three Mile Island would they be safe? **Professor F. R. Farmer**, Safety Adviser to the UK Atomic Energy Authority, discusses how to assess their dangers

FAST breeder reactor safety is currently an emotive topic, but it should be placed in context: absolute safety can never be achieved, and most industrial activities carry some risk of causing harm to people and the environment. One aim of design and operation must be to keep the risk sufficiently low, and there will be argument as to what this implies.

The increased recognition of risk has rendered obsolete the concept of maximum credible accident, and currently leads more to a discussion of residual uncertainties in accident and consequence modelling, rather than a prolonged description of the devices installed to minimise the chance of accidents and a demonstration of their reliability. In following this trend, it should be understood that some uncertainties will always remain, and it will only be possible to establish an increased degree of confidence that the system and its behaviour are well understood. This is important when considering the early versions of new systems—reactors or aircraft; it is not possible to establish the same degree of confidence in the first as may be developed by the fifth or the tenth, and to accelerate this learning process there should be extensive exchange of safety information and collaborative programmes on safety issues on an international scale. To date collaboration has been good, and it is to be hoped that commercial consideration will not prevent this exchange.

Since the fast reactor core is much more compact than thermal reactors, the heat production per unit length or volume is greater. The cooling system has to cope with this, and fast reactors use liquid sodium, a very effective heat transfer medium operating at near atmospheric pressure.

The control of power in a fast reactor is easier than most thermal reactors. Both depend on the small fraction of delayed neutrons, but the more compact core of the fast reactor simplifies the procedures for controlling power because the effectiveness of any control rod extends virtually throughout the reactor and is only slightly affected by the position of other rods. Elaborate systems of sector control, as in large thermal reactors, are thus unnecessary. It is easy to provide redundancy in the control and shut off sys-

tems, since in a large reactor with 30 rods, the insertion of any five would shut it down. The aim in current designs is to achieve sufficient diversity.

The removal of heat from the fuel in a fast reactor is in some ways easier and in others more difficult than in water or gas cooled reactors, as indicated by the following examples.

As sodium reacts violently with water—and additionally, hydrogen as a neutron moderator must be kept away from the core—all designs have intermediate sodium-to-sodium heat exchangers, and the final sodium-to-water exchangers are placed some distance from the reactor. On the other hand, the normal operating temperature of the sodium is several hundred degrees below its boiling point so that there is a wide margin to accommodate temporary disturbances of power or flow. In reactors of the tank design, the whole primary circuit is immersed in several thousand tons of sodium; as a result the fission product decay heat can be absorbed for several hours, sodium flow being by natural convective circulation. It is yet to be shown that the transition from the flow conditions under power to convective flow of a shut down reactor can take place safely—this is still being investigated.

There are several misunderstandings about the dangers of fast reactors; for example it has been said that a fast

reactor may behave like an atom bomb. The fuel of current fast reactors contains plutonium plus a higher percentage of ^{235}U , which is a neutron absorber, however, and this fuel cannot explode.

Another fear, that fast neutrons make the fast reactor more difficult to control, is likewise without foundation. The micro-second lifetime of neutrons in a fast reactor, as compared with milli-seconds in a thermal reactor, has no bearing on normal operation in which control operates through the delayed neutron fraction. Under most accident conditions the response is not dominated by the neutron lifetime, but by the doppler coefficient of the U/Pu fuel which cancels most changes in reactivity (resulting from some accident conditions) by a corresponding rapid change in the fuel temperature. The reactor becomes less reactive as the fuel temperature increases.

It has frequently been said that the particular feature of a fast reactor is that the core is not in its most reactive configuration. This is true, but it is an oversimplification in a comparison with thermal reactors. The light water reactors in their normal operation are not in their most reactive state although for different reasons. The light water reactors can be rendered prompt critical by changes in their coolant; the pressurised water reactors by a rapid temperature drop of the water; the BWR by collapse of the steam voidage in the reactor core. These conditions are now deemed to be reduced to an improbable event by design measures. The same degree of confidence has not yet been established for the fast reactor, perhaps because designs are viewed more critically. There are two types of fault conditions peculiar to a fast reactor which increase reactivity, one being the rapid expulsion of sodium from the mid-core regions, and the other a collapse or compression of the core into a slightly smaller volume.

As stated earlier, it is not, and never will be, possible to show that accidents cannot happen—it is only possible to show that the accidents are unlikely and their consequences reasonably understood and tolerable in relation to their estimated frequency.

How might this be done? It is likely that in newly developed systems such as the fast reactor, two lines will be followed in parallel. First, effective measures must be provided to prevent the escalation of minor faults into major accidents; hence all major accidents will have a very low probability of developing. Second, even if the preventative measures fail, the ways in which accidents develop and are limited and contained, are sufficiently well understood through an adequate (even if not perfect) appreciation of the

What Harrisburg means for the Rasmussen report

"I have heard recent statements that the accident at Harrisburg further devalues the Rasmussen report. I do not see any evidence for these statements; the sequence of events may or may not be consistent with the report. An accident may reveal new features and it is important to find out whether any new, unperceived sequence or new phenomena have occurred. However, the estimate of accident frequency is less important than the detailed assessment of each reactor and support systems. The chief merit of Professor Rasmussen's report lies in the detailed studies and in the control that is then exercised to ensure that his assumptions are met." **Professor F. R. Farmer.**

phenomena involved.

How far can these lines be followed at present? The normal classification of accidents into errors of control, heat removal, and so on, appear to be well covered with redundant and diverse protective equipment. The adequacy of these provisions may be subject to some discussion, mainly to improve confidence in the lower levels of accident frequency. It seems that two troublesome areas remain—a degree of uncertainty in the structural integrity of the internal reactor structures, when requiring confidence at low frequency levels, and some uncertainty in the various possible modes of failure propagation within fuel sub-assemblies and their subsequent development. Currently, many methods of early identification of onset of failure are possible, but the application of all sensors could lead to over-instrumentation to such an extent that the reactor could never operate effectively.

These uncertainties are likely to be resolved, although not solved, with sufficient confidence to enable the next stage to proceed. The greater stumbling block, ideologically, lies in the second parallel line of argument—that if preventative measures fail, the accident can still be contained. The difficulty in this approach is the continued escalation of the assumptions defining the accident. There is seldom an upper limit, and there is no maximum credible accident as conveniently postulated for the development of the light water reactors. Rather than question too closely the initiating assumptions, it may be more instructive to study two important phenomena, the mode of fuel behaviour and core dispersion in

a 'whole core accident', and the conditions of violent or passive interaction between hot fuel and sodium, known as FCI (Fuel Coolant Interactions).

The 'whole core accident' has been under study in USA, UK, France, Germany, Japan and USSR for up to 20 years. The research and theoretical programmes have been, and continue to be, extremely large and complex. The object has been to find out how fuel behaves when heated rapidly in the range 2,000 to over 4,000°C in timescales from a few milliseconds to a second or so.

Various core dispersive mechanisms exist. For a start the core must disperse if the fuel is vaporised: this mechanism can be violent and is studied to find the dynamic and static loadings in the core region and its surroundings. For some accidents, molten fuel may be swept out of the core by the coolant, and the loss of a small fraction of fuel would terminate the reactivity excursion. A third dispersive mechanism exists through internal gas pressures generated in the fuel by fission products. Theoretically, this could be very effective and could prevent fuel vaporisation, or reduce its extent. This mechanism has only been studied in the last few years, but experiments are continuing.

Fuel-coolant interactions have also been studied for well over 10 years, using various materials, including tin, aluminium, uranium oxide, water, sodium, and freon. Some theoretical correlations have been suggested in recent years, but there is not yet a generally agreed model, and more work is required particularly with UO_2 and sodium.

The question now arises of when there will be sufficient understanding of 'whole core accidents' and 'FCI', and what constitutes 'sufficient understanding'. Returning to the proposition of a two-pronged approach to safety, the first step is to show that accidents can be identified at an early stage and safely terminated—this is likely to be developed with considerable confidence. The other approach is to study accident conditions assuming protective measures fail. This route is open-ended, for at no time will it be shown that any accident developing in any way with no safeguards can be tolerated by any one design. However, these studies should lead to some optimisation in core materials, core geometry and surrounding containment, so as to tolerate a wide range of possible accidents even if these are of low probability.

This present stage in safety analysis is described by Hafele (Fusion and Fast Breeder Reactors, IAEA, A-2361 Laxenburg, Austria RR-7-8 November 1976 (Revised July 1977)) as the third stage in the safety debate. It is instructive to follow his argument. The first phase (1944–1959) gave much attention to the short neutron lifetime, the relatively small fraction of delayed neutrons, the speed of control devices, and a positive power coefficient, basically because the reactors were small and used metallic fuel. The second phase, up to 1970, considered larger reactors with mixed oxide fuel. The debate was then around the sign and size of the doppler coefficient, then around superheat, the sodium void coefficient and FCI.

The overriding feature of the third phase is a widespread and multilevel approach of proving the elements of the design concept that arose from the second phase. In this connection, one has to realise that the nature of what is considered a proof has evolved very substantially in the years since 1970. Engineering judgement is no longer considered sufficient. The probability approach to reactor safety has been introduced and related to the concept of residual risks, extremely small in probability but very large in the perceived consequences. The focus of the scientific and technical attention of the third phase is therefore the depth and credibility of the experimental and theoretical proof of the design concept. In many countries there is now a growing interest in the attempt to quantify confidence and the degree of uncertainty. This is likely to continue. □

Diagram of the core and cooling system of the UKAEA's prototype fast reactor.

This article is based on a talk given by Professor Farmer at a conference on the politics of fast breeders at the end of last year. The conference proceedings are to be published by Macmillan.

How the West was scientifically explored

The US Geological Survey celebrates its centenary this year.

Harold L. Burstyn, the agency's official historian, surveys the past 100 years

At the close of the Civil War in 1865, only three and a half million people lived in the western half of the United States. A generation later, when the Superintendent of the Census of 1890 declared that he could no longer find on the map a continuous frontier line of settlement, more than eight and a half million Americans lived to the west of the first tier of states beyond the Mississippi River. In one of history's great migrations, Americans settled 430 m acres from 1870 to 1900.

With such a headlong rush westward of people seeking new opportunity on the frontier, exploration barely kept pace with settlement. From 1867 to the end of the 1870s, four separate groups, known collectively as the Territorial Surveys, mapped the west to uncover its mineral resources and assess the uses for its land. They were independent of the General Land Office, whose locally-hired surveyors divided the land into the rectangular plots acquired by settlers.

At a much higher level of precision, the Coast Survey, founded by Jefferson in 1807 as the federal government's first scientific agency, mapped both coasts by primary and secondary triangulation. The need to connect the Pacific to the Atlantic network led to a triangulation across the country and the change of the agency's name in 1878 to the Coast and Geodetic Survey. This change took place at a time of hope for political reformers anxious to restore the good name of the United States and the Republican party after the corruption of the Grant administration. President Rutherford B. Hayes and Secretary of the Interior Carl Schurz hoped to achieve their twin aims of reform and retrenchment by consolidating the Territorial Surveys into a single organisation and placing the parcelling of land in the hands of scientists.

On Joseph Henry's death in 1878 his place as leader of the National Academy of Sciences went to O. C. Marsh, the paleontologist. Under Marsh's direction, the academy prepared at the request of the forty-fifth Congress a plan for surveying and mapping the Territories. It recommended that the work be in a single agency, the Coast and Interior Survey, which would be the old Coast and Geodetic Survey re-

Survey director Charles Walcott (left) and John Wesley Powell, with Sir Archibald Geikie, their British counterpart, at Harper's Ferry, 1897.

named and transferred from the Treasury to the Interior Department. The geological work of the separate territorial surveys, three of them still in the field, would be combined into another agency, the Geological Survey. Finally, the academy report called for a federal commission, among whose members would be the heads of both surveys, to recommend changes in the laws concerning the public lands.

The final session of the forty-fifth Congress to which Marsh and his colleagues reported met after the election of 1878. At that time bills approved in the rush to adjourn each session often contained the only substantive legislation of the entire two years of the Congress, and appropriations bills (which had to pass if the federal government was to function) were the favourite vehicles for new departures. Thus the Sundry Appropriations Bill, the last to be passed by the forty-fifth Congress, attempted to reform the disposal of the public lands by placing their measurement and appraisal in the hands of scientists. But only two of the academy's proposals were in the Bill that President Hayes signed into law just before the Congress expired at midnight on 4 March 1879: the founding of the United States Geological Survey in the Department of the Interior for "the classification of the public lands, and examination of the Geological Structure, mineral resources, and products of the national domain"; and the formation of a commission to codify and propose revisions to the land laws. Both the Democratic-controlled House and the Republican-controlled Senate rejected the attempt to change the system by which the public lands were parcelled out to settlers. And when the commission on

the land laws made its recommendations two years later, they, too, were rejected by Congress.

To direct the new Geological Survey, Hayes and Schurz chose Clarence King, leader of the Geological Exploration of the Fortieth Parallel. From 1867 to 1873, King and his civilian colleagues had reconnoitered the natural resources along the route of the first transcontinental railway and had begun a series of monographs that set the highest scientific standards for the geology of the American west. King, "the best and brightest man of his generation . . . with talents immeasurably beyond any of his contemporaries", organised the new agency into districts, headquartered in Denver, Salt Lake City, and San Francisco. His topographers and geologists spread out to determine the character of the public lands, beginning with the major mining districts: Leadville in Colorado, Eureka and the Comstock Lode in Nevada, and the gold fields of California. King hoped that a decade of concentration on the principal ore bodies would lead to a rigorous theory of their formation. A sound geological understanding of the way metals were found in the earth might also show notorious wastefulness, while the work of the geologists could help investors in American mines sort out the favourable from the unfavourable prospects.

King wanted to extend the survey over the whole country, but the Interior Department was uncertain of the survey's mandate from the Congress to study those parts of the country that did not belong to the federal government, and it confined the survey to the public lands. Frustrated by petty politics and anxious to seek his fortune in mining, King resigned in 1881.

From the Survey's archives: earthquake damage in Charleston, 1886; geologist C. Willard Hayes on the limb of an exposed syncline in Maryland, 1897.

President Garfield replaced King with John Wesley Powell. Powell and his colleagues of the Geographical and Geological Survey of the Rocky Mountain Region had found the principles of a new approach to the earth, emphasising the role of erosion and deposition in forming the landscape. As an explorer he paid as much attention to the human as he did to the natural environment. He concluded that much of the interior lacked the rainfall to support traditional family farms. Dividing the public lands into uniform rectangles would invite monopoly by whoever controlled the banks of the streams. He called for a new system of land parcelling based on topography, for the setting aside of potential reservoir sites for public ownership, and for larger homestead grants in the dry areas. Powell's ideas lay behind the projected land reform of 1879 that the Congress had rejected.

Powell abolished the district offices, and based the survey's organisation on subjects such as glacial, volcanic, and other branches of geology, rather than territory. Determined to build a national agency, he used the Congressional authorisation, "To continue the preparation of a geologic map of the United States" to expand the survey to cover the whole country. Powell countered the "states' rights" argument against his federal agency by beginning in 1884 a cooperative programme of topographic mapping with Massachusetts, which, as one of the original states, had never contained any public lands. From Massachusetts, cooperation extended into other states and into geology and hydrology until it covered virtually the whole country and all its resources. After a broad investigation of economy in the federal government's scientific agencies, the Congress in 1886 renewed the survey's mandate for earth science.

Powell's chance to press for his programme of reform came with the droughts that began in 1886. By 1888,

after drought and blizzards had destroyed the open-range cattle industry and three consecutive dry seasons had brought despair to farmers in the central Great Plains, the Congress authorised Powell to conduct an irrigation survey. He immediately began an ambitious programme, including topographic mapping of a vast area, measuring the flow of its streams, and designating the sites for irrigation works and the lands they would irrigate. The Congress closed the remaining public lands to entry until Powell and his men were finished, but this provision generated such opposition to the irrigation survey that Congress abolished all of it except the designation of sites for reservoirs. At the same time the survey suffered the first of a series of budget cuts that finally drove Powell to resign in 1894.

Though the most drastic reductions owed more to both party politics and the Panic of 1893 than they did to opposition to Powell, his colleagues and successors in the Geological Survey never forgot the lesson of the 1890s. In the United States the primary purpose of federal civilian agencies for the physical sciences (until the National Science Foundation was created in 1950) has been to regulate. As a result, in times of constraint the regulatory function can usurp the resources devoted to research, however meagre they may be. From the failure of Powell's Irrigation Survey the Geological Survey's leaders learned that science could be saved only if administrative power was eschewed. For the next 30 years, they ensured that all possible regulatory roles were transferred to other agencies. As a consequence, its leaders believe, "the government's most productive research agency during the nineteenth century" has maintained its vitality in scientific research into the final quarter of the twentieth.

The trees of the United States passed rapidly into private hands until 1891

when the lame-duck fifty-first Congress empowered the President to create forest reserves by removing timbered lands from the market. Under Powell's successor, Charles D. Walcott, the Geological Survey mapped these national forests. Walcott also continued the Survey's inventory of the nation's water supplies.

As the vast fields of coal began to power the rapidly growing US industry, the Geological Survey began to test coals for their heating value and rocks for their use as structural materials. In 1908 the Congress asked the survey to look into mining safety, but since it was still averse to a regulatory role, these tasks were both transferred by the Congress to the Bureau of Standards and the newly-created Bureau of Mines.

Only in 1927, towards the end of the longest term of any of the survey's ten directors, George Otis Smith, did the survey abandon its opposition to becoming a regulatory agency. In 1925 Secretary of Commerce Herbert Hoover had wrested the Bureau of Mines out of the Interior Department into his own. The responsibility of the Bureau of Mines for supervising mining on public land was moved to the Survey's Land Classification Branch which became the Conservation Branch. With the growth of oil production on the outer continental shelf, the Geological Survey's Conservation Division is now its fastest-growing part.

The present Geological Survey continues to map the topography and the geology of the far-flung United States, to test its waters for quality and quantity, and to investigate the processes which formed the earth and the planets. The research ideal that has animated the US Geological Survey has borne fruit for a century. Yet the goal for which the Survey was founded—to make science the basis for the use of the land and its products—has not yet been reached. It remains the goal for the Survey's second century. □

Dismantling DNA regulations

SIR,—I am delighted that John Maddox has taken up the debate on the problems related to regulations governing genetic manipulation (1 March, page 10). His analysis of the situation is perceptive when he states that the choice, if GMAG's procedures don't change soon, will be only whether to work with NIH guidelines here or elsewhere. In this regard John Maddox and I probably disagree only on time scale. He clearly feels that all may be resolved by the end of 1980 and asks if this is not enough, is it "a chance worth taking"?

If we are going to gamble we must know the odds and the stakes. At stake is the future of most genetic manipulation work in this country. The odds are heavily against anyone trying to continue in this highly competitive field if work has to be conducted under regulations so much more restrictive than elsewhere.

It is particularly bitter irony to find myself grouped with those scientists who invited constraints four years ago. That group was dominated by US scientists who are now working under relaxed NIH guidelines, while their colleagues here languish in the aftermath of their public outburst. From the outset, I have thought that those who invited constraints were doing both science and the public a huge disservice; I see no evidence to change my mind. A bureaucracy has been established and will be hard, if not impossible, to dismantle rationally.

In attacking the NIH guidelines, John Maddox subscribes to currently fashionable scare stories, those of "conjectured immunological hazards" and other problems "of expression". In fact when we talk of known proteins we can estimate possible dangers because we handle the proteins in their regular environment. We can therefore assess how to take precautions in handling the same products in genetic manipulation experiments. Such decisions, at least at the research laboratory level, are a matter of day-to-day care and not a matter for committee rulings and elaborate bureaucratic procedures. If there were risks which could be quantified and if there were a need for regulations which which could be formulated rationally, then we might start to build from scratch. Unfortunately, we are not in a position to build, but rather in the position of dismantling excessively restrictive, empirically conceived, regulations.

If we were to accept the idea of dismantling the regulations by rational means we could fall into an expensive trap. Any conjectured risk would need to be quantified and the limit to conjecture and to expense involved in collecting the necessary data cannot be foreseen. What I asked for previously was an acceptance of the spirit of the NIH guidelines. Let us recognise the need for care when there is a known hazard, but let us not get lost in a morass of conjectured risks.

Yours faithfully,

ALAN R. WILLIAMSON

Institute of Biochemistry,
University of Glasgow, UK.

Mediterranean scientists stymied by bureaucrats

SIR,—Rather than focus on who attacked UN research programmes on the Mediterranean at the recent Geneva Conference of the Mediterranean States (15 February, page 506), and who succeeded in cutting three scientific research projects of major importance, one should analyse who failed (and why) to support the scientific component of the Mediterranean Action Plan (MAP). Incidentally, this component has been fully in line with the proclaimed "target areas" of the Group of 77 and of the UN system, among which the "reinforcement of scientific and technological capacities of the developing countries" is foremost.

That research results, produced by the 83-odd laboratories of the region, are still inferior in quality compared to those from (for example) Liverpool, Woods Hole, or Villefranche-sur-Mer, would hardly surprise anybody. Obviously, in recent years something different from competing with the centres of excellence has been attempted. Recently it became clear that this implicit aim has met with considerable success. At the November 1978 joint ICSEM-UNEP Review Meeting on the Mediterranean Pollution Research Pilot Projects, held at Antalya, Turkey, a large number of interesting contributions were reported. These came from many laboratories never before known to produce anything of international significance. UNEP's contribution to the execution of these programmes was in the form of equipment, training fellowships, and travel and subsistence support for such meetings. It never amounted to more than some 10% of the total on-the-spot expenditure for the participating laboratories' projects. However, its importance should be judged by the fact that it mobilised sizeable national resources for research in marine sciences in many developing countries; but, unfortunately, not in all. The latter, instead of asking for additional help in creating national research centres, have joined the ranks of critics of the programmes, although for different reasons.

The UNEP-sponsored and -catalysed multilateralism in scientific training, technical cooperation and data exchange, has indicated, for better or worse, the eclipse of the old northern paternalism. Even the well produced 'show-biz' contribution to the Antalya meeting by one of the most developed countries of the region, has not, and probably would not reverse this trend. It has become apparent that all around the Mediterranean there is emerging a broadly based international community of marine scientists, which is procuring the necessary atmosphere for appraisal of scientific data, for discussion of results, and for mutual understanding irrespective of present day political or economic disagreements. The bureaucrats, a large majority in the ranks of the 60, or so official governmental representatives at the Geneva Conference, have seen the old, more-or-less comfortable, order vanish,

and see themselves increasingly made superfluous by the internationally oriented groups of scientists. The latter, as well known from experience, are difficult to control: they will soon be asking for more money, and will generally become a pain in the neck. Thus the hatchet was used, not surprisingly, on those who have produced the only tangible result in the four years of this unique exercise called MAP. Conversely, and in line with this thinking, a boost has been given to appealing, but vaguely defined, future plans. Among these, as Dr Walgate has correctly indicated, the development of alternative energy sources by the less developed countries has been accepted as one of the short term priorities.

The Geneva Conference was, in a way, a scaled down rehearsal for the UNCSTD. The message is clear and fully supports Moravcsik's admonition: do not let scientific and technological issues be decided by bureaucrats alone.

Yours faithfully,

VELIMIR PRAVDIC

Zagreb, Yugoslavia.

Cooperation in German health programme

SIR,—In his article about research in Germany (8 February, page 423) Robert Walgate refers to the federal government's programme on promoting research and development in the service of health 1978-1981 and to some worries of officials of the German research society (DFG). I am afraid there has been a misunderstanding, since there is no conflict between DFG and the federal ministries responsible for the health research programme.

When setting up the government programme, DFG and the federal government agreed that a close cooperation should take place. This is routine by now, DFG officials taking part in assessment meetings and quite often making valuable suggestions. In addition to this we have asked DFG to inform the government whenever they have the feeling that a project in health research is being funded by the federal government although the scientific quality does not seem to be sufficient. No example has been reported so far.

It is obvious that only research of good scientific quality should have an impact on government policy: poor research would do more harm than good. However, the federal ministries reserve the right not to fund a research project if it is likely that possible results would not have any bearing on the work of the ministries. In these cases, which happen quite often, the applicants are advised to submit their proposals to DFG or other institutions which do not have the same restrictions as we have, and whose financial means are not changed by the arrival of the new programme.

Yours faithfully,

HANS P. LORENZEN

Federal Ministry for Research and
Technology, Bonn, West Germany.

Plant protection

SIR,—Your correspondent writing on 'European plant health' (4 January, page 16), draws attention to and criticises certain aspects of the policy of the European and Mediterranean Plant Protection Organisation (EPPO) in listing organisms of plant quarantine significance for the EPPO region and describing them in its data sheets.

It is the function of EPPO to advise member governments on the technical, administrative and legislative measures necessary to prevent the introduction and spread of pests and diseases of plants and plant products. Thus it does through the agency of its working party on phytosanitary regulations, made up of specialists from nine of the 35 EPPO countries. The working party is, with the full approval of Council, developing procedures in three distinct areas. The first of these is the formulation of lists of non-European (A1) and European (A2) pests, based on extensive research data and the common experience of the plant health services of 35 member countries. The purpose of these lists is to draw the attention of countries to the organisms considered of greatest quarantine importance to the EPPO region so that appropriate precautions are taken in the form of stringent regulations. The second stage is the preparation, for each listed organism, of 'specific quarantine requirements', which EPPO countries are recommended to use as a basis for their phytosanitary regulations. These requirements are addressed specifically to the exporting country and specify conditions which have to be met for the importation of particular plants and plant products, based on the most detailed knowledge available on ease of detection of quarantine organisms in consignments and in the field, on persistence in soil, and so on. It is the formulation and acceptance of these recommendations as a basis for phytosanitary regulations which is the backbone of EPPO's international strategy to ensure that correct and adequate precautions are taken to prevent as far as possible the introduction of new pests without bringing the international exchange of commodities to a standstill. The third element is the preparation of data sheets on the A1 and A2 organisms. These sheets are addressed to a wider readership, including on the one hand the plant inspectors of importing and exporting countries and on the other, the general scientific public, which should be better informed on these organisms, many of which are poorly documented at present. Further details on the activities of EPPO and its working parties will appear in the proceedings of a conference (Plant Health: the Scientific Basis for Administrative Control of Plant Parasites, ed D. L. Ebbels & J. E. King) to be published by Blackwells for the Federation of British Plant Pathologists.

At all stages in the formulation of the A1 and A2 lists and in the preparation of specific quarantine requirements and data sheets, extensive consultations have been made with research specialists in the EPPO region and throughout the world. The exact status of some potentially dangerous diseases of virus, or virus-like, origin is less certain than that of most of the organisms on the EPPO lists. These uncertainties, which will doubtless be resolved by further research, are clearly stated in the EPPO data sheets and will similarly be reflected in the appropriate

specific quarantine requirements. The problem of new strains of quarantine organisms is a very difficult one, which has been thoroughly considered by the working party and can only be resolved at present by applying requirements to all those entities which are indistinguishable in inspection practice from the dangerous ones, or, in extreme cases, by prohibiting the importation of certain plants. It is impossible to foresee the appearance elsewhere in the world of a new aggressive strain of a pathogen already present in a country. Phytosanitary regulations can only be formulated in practice in terms of what is known to exist, not what might exist or appear. This also applies to pesticide-resistant strains, which may cause considerable trouble when introduced into new areas.

We believe that EPPO's phytosanitary strategy, which has been formulated by and has the support of the plant health services of its member countries in consultation with their own specialists, is a sound basis from which to tackle the practical problem of excluding dangerous pests from the region at a time when increasing quantities of exotic products from many parts of the world are being shipped to Europe in fast-moving freight transport. The A1 and A2 lists are under constant review and will be extended as necessary to include other quarantine pests as information on their importance becomes available. If the formulation of the lists and the publication of the data sheets encourages research workers to try to resolve some of the uncertainties about these pests, so much the better.

Yours faithfully,

A. H. STRICKLAND
G. MATHYS
P. JOURNET
JAC FJELDDALEN

EPPO, Paris, France.

Safety in the news

SIR,—Perhaps some other readers noticed a remarkable coincidence of news items in the 8 March issue of *Nature*.

First there is the ban, after a ten-year struggle, of the 2,4,5-T herbicide in the US, because of the presence of dioxin. Then there is the recent release of the file on past nuclear reactor incidents, with the official comment "the absence of more serious effects is largely the result of luck", and the occurrence of accidents with a Rasmussen probability of 10^{-12} per year. Also, there is the new official concern in the US with the potential dangers of low levels of radiation previously treated as safe.

Finally, J. D. Watson calls for the deregulation of all DNA research, not merely that on a laboratory scale of the past few years, but also the industrial-scale research of the future.

Yours faithfully,

J. R. RAVETZ

University of Leeds, UK.

Detecting frozen lunar gases

SIR,—The possibility of sending a lunar satellite into a polar orbit round the moon is being discussed. This will allow the observation of the interiors of craters near the poles, the bottoms of which may never have been reached by the sun since their time of formation. I have suggested earlier (*Phys. Bull.* 24, 312 and 453; 1973)

that in such cold crater bottoms one might find a continuous record of the evolution from the moon's interior of gases such as water, carbon dioxide, and many other materials volatile at lunar day-time temperatures.

In the absence of a significant permanent atmosphere on the moon, individual molecules will travel over a large part of the lunar surface; any which are not swept away by the solar wind or by becoming ionised will eventually find their way to a cold crater and freeze out there. The deposited strata of condensed gases cannot be studied without the landing of appropriate instruments, but the orbiter may make it possible to identify likely places for this.

Over the whole lunar surface, one could expect the top metre of regolith to contain something like fifty million curies of uranium. A large part of the radon-222 derived from the decay of this should be able to escape and with a $3\frac{1}{2}$ day half-life has a good chance of reaching the polar region before it decays. An atom of radon would be held in a sunless area and such an area will therefore concentrate the radon itself and its daughters from a much larger area. An observable amount of alpha-activity might therefore be concentrated although good spatial resolution would be needed to observe it. Detection would be made easier by the fact that the emission would be effectively from an infinitely thin source since the cold condensed layer would be thick enough to stop all alpha-particles from the underlying long-lived alpha-emitters. It might, however, be worth looking carefully at the energy distribution of the alpha-particles of polonium-210 which, together with its parent lead-210, could be expected to have remained in situ for some decades, during which there might have been some deposition of a detectable thickness of water if there had been any significant emissions of this during the period.

Over most of the lunar surface one would of course expect a thick-source spectrum derived from alpha-emitters still within the regolith with only a small thin-source contribution from the radon in the "gas phase" above the surface. A limit to the relative size of this may be estimated. The mean thermal velocity of ^{222}Rn at 0°C is about 160 m s^{-1} . Leaving the moon's surface normally with this velocity and without collision it would fall back to the surface again in 200 seconds. An average excursion would take about two minutes during which time it would travel horizontally about 20 km. In an average lifetime of five days it could thus make some 3,500 returns to the surface, and a cold crater bottom could expect to collect all the radon from 3,500 times its own area.

This figure must certainly be too high since it assumes an effective albedo of one, or zero resorption by the rest of the surface. This is quite unrealistic. The time of dwell on or in the surface after each return is not known but is clearly not zero. On the other hand, if the satellite could be made to travel well below the top of the radon atmosphere (half height nearly 10 km) the background of thin-source particles would be usefully reduced. All in all, it would certainly seem worthwhile to look for possible anomalies of alpha-emission near the poles.

Yours faithfully,

J. H. FREMLIN

Acetylcholine receptor clusters

from Eric Frank

THE acetylcholine receptor, a membrane protein that mediates transmission of information between nerve and muscle, has been extensively studied both physiologically and biochemically. Yet despite the wealth of available information concerning its distribution, pharmacological properties, synthesis, degradation and subunit structure, one still knows very little of how receptors come to be so precisely located at neuromuscular junctions. Small clusters of ACh receptors found on non-innervated muscle cells resemble the high density patches at synapses, and a knowledge of how these receptor clusters are formed may provide some insights into the development of the postsynaptic muscle membrane.

In mature muscles, the sensitivity to ACh falls 50 to 100 times when the point of ACh application is moved only 2 μm away from a nerve terminal, and within 100 μm the sensitivity is down by more than a factor of 1,000 (Kuffler & Yoshikami *J. Physiol. Lond.* **244**, 703, 1975). Anatomical studies using α -bungarotoxin as a specific, high affinity ligand for cholinergic receptors in vertebrate muscle have shown a similar degree of localisation of the ACh receptor to neuromuscular synapses (Barnard, Wieckowski & Chiu *Nature*, **234**, 207, 1971; Hartzell & Fambrough *J. gen. Physiol.* **60**, 248, 1972; Albuquerque, *et al.* *Proc. natn. Acad. Sci. U.S.A.* **71**, 1376, 1974; Fertuck & Salpeter, *J. Cell Biol.* **69**, 144, 1976). The distribution of ACh receptors on muscle fibres without a well established innervation is markedly different, however. Denervated, embryonic and neonatal muscles all have high densities of receptors over their entire surface (Katz & Miledi *J. Physiol. Lond.* **162**, 393, 1962; Diamond & Miledi **170**, 389, 1964). Until recently, extrasynaptic receptors in denervated and embryonic muscle

were thought to be uniformly distributed in the muscle membrane. With the idea of membrane as a fluid mosaic (Singer & Nicholson *Science*, **175**, 720, 1972), a reasonable model was that a motor nerve somehow kept the receptors organised in a cluster at synapses, but that in the absence of this neural influence, the receptors were randomly distributed throughout the membrane.

It came as some surprise, therefore, when ACh receptors on muscle cells cultured in the absence of nerve cells were found to be clustered (Vogel, Sytkowski & Nirenberg *Proc. natn. Acad. Sci. U.S.A.* **69**, 3180, 1972; Fischbach & Cohen *Devl Biol.* **31**, 147, 1973). The clusters were present even if special precautions were taken to ensure that the muscle cells had not been contacted by nerves *in ovo* before they were isolated and put into culture (Beckoff & Betz *Science*, **193**, 915, 1976). Since the discovery of receptor clusters on myotubes *in vitro*, they have been observed in extrasynaptic regions of denervated mammalian muscle *in vivo* as well (Ko *et al. Science*, **196**, 540, 1977).

Characteristics

Clusters of ACh receptors, often called hot spots because of their high sensitivity to ACh, are typically round or ovoid patches about 5–10 μm across. In culture, each myotube usually has at least one cluster, more commonly two or three, and two clusters can occur in close proximity. Patches occur both at the edges of cells and in the thicker, more central regions where they are frequently associated with a muscle nucleus (Fischbach & Cohen *Devl Biol.* **31**, 147, 1973; Anderson *et al. J. Physiol. Lond.* **268**, 731, 1977). They are found on both cell surfaces, either juxtaposed to the substrate or on the free surface. Most clusters have discrete boundaries, the receptor density falls to background levels within a couple of micrometres. Estimates of receptor density within a cluster made using radiolabelled α -bungarotoxin are

two-to-threefold lower than those at mature synapses (Sytkowski *et al. Proc. natn. Acad. Sci. U.S.A.* **70**, 270, 1974). Freeze-fractures of identified hot spots also show a particle density two or threefold less than at neuromuscular synapses (Yee *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 3007, 1978). In myocytes of *Xenopus*, receptors in hot spots are grouped into many tiny spots or fine lines (Anderson *et al. op. cit.*). Given this uneven distribution, the peak density within a hot spot may be as high as in mature postsynaptic membrane. One ultrastructural study failed to demonstrate any unique membrane or cytoplasmic specialisation at receptor clusters, but the immunoperoxidase method used may have obscured some fine details (Vogel *J. Cell Biol.* **69**, 501, 1976).

Hot spots increase in number throughout the first week in culture (Sytkowski *et al. op. cit.*). Once formed, they are stable structures. Only rarely does a cluster move or disappear on a morphologically stable muscle cell (Anderson *et al. op. cit.*; Frank & Fischbach *Cell and Tissue Interactions*, (eds Lash & Burger) 1977), although their total number does decrease in older cultures (Prives *Cell*, **7**, 543, 1976). After the initial stage of cluster formation, the appearance of a nerve fibre has not been observed on morphologically stable muscle cells. This positional stability is correlated with a lateral stability of individual receptor molecules in a cluster. By labelling receptors with fluorescent α -bungarotoxin, Podleski and his collaborators showed that receptors within a cluster are not free to migrate within the plane of the membrane, whereas receptors not associated with a cluster can diffuse quite readily (Axelrod *et al. Proc. natn. Acad. Sci. U.S.A.* **73**, 4594, 1976). Clustered receptors are not metabolically stable, however. Twenty-four hours after receptors are irreversibly blocked with toxin, hot spots reappear at their previous locations (Frank *et al. Neurobiology*, (eds Otsuka & Hall)

Eric Frank is Assistant Professor of Neurobiology in the Department of Neurobiology, Harvard Medical School, Boston.

1979). Thus individual receptors within a cluster are being constantly replaced even though the cluster as a whole is stable.

Receptor clusters share several characteristics with the subneural patches at nerve-muscle synapses in culture. Both types of cluster are positionally stable over time, although they can disappear if the muscle cell is innervated at another location. Individual receptor molecules are present at a similar density and are metabolised relatively rapidly, with a half-time in the membrane much shorter than at adult neuromuscular junctions but comparable to that of non-clustered receptors (Schuetze *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 520; 1978). The only consistent difference that has been noted is that in cultures of nerve and muscle from *Xenopus* larvae, neural patches tend to be long and narrow, similar in shape to the overlying neurite, while aneural patches are circular or oval.

Significance of receptor clusters

Almost as soon as receptor clusters were discovered, it was hypothesised that they might serve as recognition sites for cholinergic nerves innervating muscle (Fischbach & Cohen *Devl Biol.* **31**, 147; 1973; Vogel *et al. Proc. natn. Acad. Sci. U.S.A.* **70**, 270; 1973). Under a variety of conditions, neuromuscular synapse formation is correlated with a high density of ACh receptors, both during embryonic development and during the reinnervation of denervated muscle. Clusters of ACh receptors on cultured muscle cells therefore might act as preformed postsynaptic sites. A cholinergic nerve, encountering a receptor cluster would form a synapse there.

This idea, however, turned out to be wrong. Work from two different laboratories using different animals and different methods are in full agreement that most, if not all, nerve-muscle synapses do not form at pre-existing receptor clusters. M. Cohen and his collaborators used fluorescently labelled α -bungarotoxin to follow the distribution of receptors during synapse formation on myocytes cultured from *Xenopus* larvae (Anderson *et al. op. cit.*; Anderson & Cohen *J. Physiol. Lond.* **268**, 757; 1977). The fluorescent patches under nerve processes, presumably at synapses, were very different in shape from those on myocytes uncontacted by nerve cells. In a few cases, the distribution of receptors was followed on a single myocyte while it was contacted by a neurite. Receptor molecules already labelled with fluorescent toxin coalesced under the neurite, and adjacent pre-existing fluorescent patches often disappeared. Neural clusters were thus formed by re-

cruitment of surrounding unclustered receptors, and perhaps by receptors from dispersed pre-existing clusters as well. Similar results were obtained in G. D. Fischbach's laboratory where the ACh sensitivity profile of chick myotubes in culture was determined physiologically during innervation by explants of embryonic chick spinal cord (Frank & Fischbach *Neurobiology*, (eds Otsuka & Hall) 1979). New areas of high sensitivity appeared at newly formed synapses. In no case was a synapse observed to form at a pre-existing sensitive spot. These pre-existing clusters often disappeared when they were adjacent to synapses, just as observed in the cultures of amphibian muscle. Because of the method used to assay ACh receptor distribution, it could not be determined whether receptors were recruited from adjacent areas or represented the incorporation of new receptors into the postsynaptic membrane.

It should be stressed that these findings do not bear on the importance of ACh receptors during synapse formation. There are appreciable numbers of receptors everywhere on these cultured muscles, at a density comparable to that in extrasynaptic regions of denervated, supersensitive muscle. Nor should one conclude that there are no preferred sites of innervation. If such sites do exist, however, they are not characterised by clusters of ACh receptors.

Another possibility is that receptor clusters on non-innervated muscles do not serve any useful function but are produced by the same mechanisms that operate during synapse formation to form high receptor densities in the postsynaptic membrane. During synapse formation, a nerve could simply trigger off an innate mechanism in the muscle resulting in the creation of a subneural cluster. Under normal conditions *in vivo*, motor nerves are present at very early stages of myogenesis, so that receptor clusters might normally appear only at synapses. But in culture, where muscle can be grown in the absence of nerve cells, cluster formation might be inappropriately triggered by other factors. Consistent with this idea is that synaptic and aneural receptor clusters in culture appear to be very similar to each other.

How nerves induce receptor clusters is unknown. An old theory was that ACh itself acted as a trophic agent, keeping the receptors clustered at the synapse. More recently, it has been suggested that the mere physical presence of the nerve could produce a high receptor density, since a thread or dead nerve placed on the surface of a muscle can produce a local area of high sensitivity. However, recent experiments by M. Cohen show that

clusters do not form under sensory nerves (personal communication). The most promising current idea is that motor nerves release a chemical substance other than ACh that induces receptor accumulation and/or cluster formation. Three laboratories have reported that extracts of nervous tissue added to muscle cultures increase the number of ACh receptors (Podleski *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 2035; 1978; Christian *et al.* **75**, 4011; 1978; Jessel *et al. Neuro Abs.* **4**, 369, 1978) and at least one of these extracts increases the number of receptor clusters as well. The isolation of the relevant substance in these extracts may provide an important tool in the study of the molecular mechanisms of receptor clustering. □

Cell lineage in early development

from Jonathan Slack

THE days of descriptive biology are often thought to be over, but in the field of experimental embryology there is a type of pure observation which retains its importance and which continues to pose considerable technical difficulties. This is the construction of the 'fate map' for an animal embryo, which shows what will happen to each region of the embryo during normal development. An accurate fate map is essential for the correct interpretation of experiments which seek to establish the causal relations of development by interfering with the normal processes.

Only a limited amount of information can be obtained by the direct observation of embryos because of the complexity of cell numbers and morphogenetic movements, although it has been possible to trace the cell lineage of the nematode *Caenorhabditis elegans* up to 182 cells by Nomarski optics (Deppe *et al. Proc. Natn. Acad. Sci. U.S.A.* **75**, 376; 1978). So the technical problem is that of specifically labelling a certain region of the embryo in such a way that the progeny of the marked cells can subsequently be found and identified, and to do this without damaging the marked cells or otherwise perturbing normal development. The methods used in the past have included staining with vital dyes, application of extracellular carbon particles and insertion of homologous

Jonathan Slack is a developmental biologist working at the Imperial Cancer Research Fund's Mill Hill Laboratory, London

grafts whose cell nuclei are labelled with ^3H -thymidine or with a chromosomal marker. Much has been done with these methods, particularly on the amphibian and chick embryos, but each has its own limitations and disadvantages and in particular it is not often possible to mark single cells in the early embryo.

A technique has recently been introduced which seems to offer considerable scope for the construction of accurate fate maps for several types of embryo and which is particularly suitable for the marking of single cells. It is described in a paper by D. A. Weisblat, R. T. Sawyer and G. S. Stent (*Science* **202**, 1295; 1978). The marking is carried out by the injection of horseradish peroxidase (HRP) into one of the large cells arising from an early cleavage division (blastomeres). The embryo is then allowed to develop for a certain time during which the enzyme persists passively in the cytoplasm of the daughters of the injected blastomere. When the embryo has reached the desired stage it is fixed and the regions containing the peroxidase can be visualised by standard histochemical procedures, either in whole embryos, if they are small enough, or on frozen sections. In this paper the fates of various early blastomeres of the leech *Helobdella triserialis* are traced. The enzyme persists in the appropriate clones for several days in an active form and it does not seem to interfere with normal development. HRP has a molecular weight of 40,000 and would not therefore be expected to pass from cell to cell through gap junctions. By contrast it is shown that a low molecular weight fluorescent dye, lucifer yellow, does spread to the whole embryo after injection into a single blastomere.

The technique has been applied to the early amphibian embryo by M. Jacobson and G. Hirose (*Science* **202**, 637; 1978; *Zoon* **6**, 149; 1978). When one of the first two blastomeres of *Xenopus laevis* is injected the whole of the appropriate side of the embryo can subsequently be shown to be labelled. In only one organ is there any contribution of cells from the contralateral side and this is the ventral part of the retina which is found to consist on both sides of a mixture of labelled and unlabelled cells. By means of injections of single blastomeres at 4, 8 and 16-cell stages it is shown that only the dorsal blastomeres contribute to the neural plate and that within the neural plate the clones make up longitudinally arranged strips.

These authors also make use of mosaic embryos which are produced by subjecting newly fertilised eggs to a heat shock. This causes suppression of

the second polar body and in a small proportion of cases leads to a situation in which the first two blastomeres contain different numbers of chromosome sets. This difference of ploidy is visible in the progeny clones as a difference of cell size and nuclear staining intensity. The results obtained from this method with respect to the shapes of clones and the provenance of the retina are substantially the same as those obtained from the HRP procedure, but the introduction of mosaics for the fate mapping of amphibia focuses attention on a rather important aspect of the interpretation of these maps. This is highlighted by another technique known as gynandromorph mapping which has been used to produce fate maps for the blastoderm stage of *Drosophila simulans* and other insects (reviewed by Janning in *Genetic Mosaics and Cell Differentiation*, Springer-Verlag, 1978). This also depends on the production of a mosaic after the first nuclear division, but in contrast to *Xenopus* in which the first cleavage is usually in the median plane for all embryos, in the insect the first

nuclear division is randomly oriented. So the early stages have no definable fate map because different individual embryos are different, and the mapping is carried out with respect to the later, blastoderm, stage by statistical inference from the frequencies with which adult structures appear within the same clone.

This dramatic difference between two types of animal embryo: one with reproducibly oriented early divisions and the other without, should help clear up a misconception often found in the literature. It is often assumed that an account of a cell lineage which does not vary between individual embryos gives some information about the decisions made during development and the states of determination of the cells. But it does not. As fate mapping is a purely descriptive procedure, additional investigations must always be made to establish whether clonal boundaries separate regions of different intrinsic cellular characteristics or whether they are simply passive consequences of the orientation of early cleavages. □

Specificity of DNA uptake in bacterial transformation

from J. R. Saunders

THE genetic transformation of bacteria by purified DNA has been of great significance in the development of molecular biology and is an essential technique in recombinant DNA research. However, little is known of the overall importance of transformation as a means of genetic exchange between wild populations of bacteria. Some bacterial species such as *Streptococcus pneumoniae*, *Bacillus subtilis*, *Haemophilus influenzae* and *Neisseria gonorrhoeae* become naturally competent (able to bind and take up DNA into a DNase-resistant form) in particular growth conditions. This suggests that gene transfer by transformation may be a relatively frequent event in the biology of these organisms.

B. subtilis or *S. pneumoniae* can take up DNA from unrelated (hetero-specific) organisms as well as homo-specific DNA. On the other hand *H. influenzae* can discriminate against foreign DNA and will only take up *Haemophilus* DNA efficiently (Scocca *et al.* *J. Bact.* **118**, 369; 1974). Two elegant papers from Hamilton Smith's laboratory at Johns Hopkins have re-

cently provided some exciting insights into the mechanisms involved in the specificity of DNA transport during *Haemophilus* transformation. Sisco and Smith (*Proc. natn. Acad. Sci. U.S.A.* **76**, 972; 1979) have examined transformation specificity in *H. influenzae* using as a probe an 8.1 kilobase fragment of *H. parainfluenzae* DNA cloned in *Escherichia coli* on the plasmid pBR322. This fragment was adsorbed very well by competent *H. influenzae* cells whereas pBR322 DNA was not. Recognition of *Haemophilus* DNA could not possibly involve conventional restriction/modification systems because the probe DNA had been propagated in *E. coli* and would have lost the specific *Haemophilus* modification pattern. It seemed likely therefore that *Haemophilus* DNA contains a special base sequence which determines uptake. Sisco and Smith then located these putative sites of specificity on two smaller fragments (120 and 140 base pairs long) lying 3.8 kb apart on the restriction endonuclease cleavage map of the 8.1 kb fragment. Competition for binding to *H. influenzae* cells between labelled 8.1 kb fragment DNA and chromosomal DNA from *H. influenzae* or *H. parainfluenzae* indicated that the *Haemophilus* genome contains

J. R. Saunders is a Lecturer in the Department of Microbiology, University of Liverpool.

about 600 copies of this uptake sequence (approximately 1 site per 4.0 kb). This specificity site does occur in certain heterologous DNA species but only at a low frequency (about 1 site per 300 kb). This limits successful uptake to fragments of foreign DNA carrying the recognition sequence. The actual recognition site is estimated to be only 8–12 bases long but the exact sequence awaits elucidation.

The ability to recognise the uptake sequence apparently resides in a membrane protein which is capable of specific binding of *Haemophilus* DNA and which is found only in competent cells (Deich & Smith in *Transformation 1978* (eds. Glover & Butler) 343, Cotsword Press, Oxford; 1979). This protein could merely be a specific surface receptor for DNA but it might also act as a pilot protein guiding homologous DNA into the cells. It is worth noting that a surface-located endonuclease is required for transformation of *S. pneumoniae* where one strand of double-stranded transforming DNA is degraded whilst the complementary strand is drawn into the competent cell (Lacks in *Microbial Interactions. Receptors and Recognition. Series B.* 3, 179; 1977). However, the situation must be different in *Haemophilus* because DNA remains double-stranded for several minutes after uptake and there is no evidence as yet that the receptor protein has nuclease activity.

A paper from the laboratory of Alexander Tomasz at the Rockefeller University, New York shows that *N. gonorrhoeae* also has a system for discriminating against foreign DNA during transformation (Dougherty *et al.* *Biochem. biophys. Res. Commun.* 86, 97; 1979). Gonococci will adsorb large amounts of both homologous (*Neisseria*) and heterologous DNA but only the former is taken up into a DNase-resistant (presumably intracellular) form. Competition experiments suggest that gonococci have two kinds of receptor on the cell surface. One receptor binds all types of DNA and the other is specific for DNA from closely related species. DNA is transported into the cell solely from the latter receptor. Whether or not the molecular basis for the specificity observed in *N. gonorrhoeae* is similar to that found in *Haemophilus* remains to be seen.

The specificity of DNA uptake exhibited by *H. influenzae* and *N. gonorrhoeae* raises some interesting possibilities as to the role of transformation in natural populations of these bacteria. Both organisms are prone to autolysis, releasing DNA, and both are highly competent, suggesting that transformation may often occur in the wild. Efficient transformation, however, poses its own problems since indiscriminate uptake of heterologous DNA on a large

scale could swamp restriction systems and compromise the genetic integrity of the host. Surface-located systems for distinguishing homologous DNA may therefore have evolved as additional genetic isolating mechanisms. Even so other bacteria which are also readily transformed *in vivo* such as pneumococci have maintained their species identity without the benefit of a discriminatory uptake system for DNA. The origin and evolution of specificity sites in *Haemophilus* together with possible similarities with restriction endonuclease recognition sites should become more apparent when their full base sequence is known. The specificity of *Haemophilus* transformation is, however, evidently yet another example of the ability of proteins to recognise defined sequences in DNA. □

Myofibrillar connection

from Pauline Bennett

It has long been suspected that in the striated muscle fibre there is a cytoskeleton which holds the constituent myofibrils in place. The presence of structural elements parallel to the fibre axis is indicated by the elastic resistance of the muscle to stretch which is not attributable to the contractile apparatus itself. Further, when the bulk of myosin and actin are extracted from myofibrils there remain 'ghosts' whose integrity is not lost even though in the light microscope only the Z-disks can be seen. The presence of transverse elements is suggested by the tendency for the Z-disks of neighbouring myofibrils to be in axial register across the fibre giving rise to the cross-striated appearance of the muscle cell. The components of this framework have not until recently been identified.

There have been suggestions, usually based on electron micrographs of muscle from which the contractile proteins have been extracted that a fibrous element is involved. For example, from such observations and an investigation of the components of extracted muscle, Maruyama and his colleagues (*J. Biochem.* 82, 317; 1977) consider that there is present a framework of longitudinal elastic filaments around each myofibril and that these filaments are composed of a protein, connectin. Connectin is however insoluble and has proved difficult to characterise.

In micrographs of intact muscle such

filaments are not in general observed, only membranous material is seen lying between the myofibrils. These membranes are obvious candidates for a supportive role. The sarcoplasmic reticulum sheaths each myofibril and could contribute to the longitudinal element whereas the transverse (T) tubule system is invaginated across the muscle fibre and could form the transverse elements. Furthermore the T-tubules occur at very precise positions with respect to the sarcomere structure, this position depending on the source of the muscle. In avian and amphibian skeletal muscle the T-tubules circle the myofibril at every Z-disk level and this relationship is maintained during contraction of the muscle. The question therefore is, what structural links are there, if any, between the membrane system and the contractile apparatus? One component of the transverse links seems now to have been identified.

Lazarides and his colleagues in a recent series of papers have been investigating the role and distribution of a protein they call desmin (from the Greek *desmos*, a link). This protein of chain weight 55,000 they first found in chicken smooth muscle. They have shown by indirect immunofluorescence that its antibody labels structures in all avian muscle cell types including the Z-lines of skeletal muscle fibres. Now Granger and Lazarides (*Cell* 15, 1253; 1978) have studied in more detail the three-dimensional distribution of antibody binding in striated muscle. To do this they have been aided by the valuable discovery of a method for obtaining sheets of Z-disks. Whole muscle, when homogenised, tends to be sheared lengthwise to form myofibrils. However, if most of the myosin and actin are first extracted from the muscle with KCl and KI the axial strength is reduced and blending shears the fibre across its width giving honeycomb-like sheets of Z-disks. SDS gel electrophoresis shows that these sheets are enriched in desmin compared with the original muscle although they still contain substantial amounts of actin, some α -actinin and traces of myosin and tropomyosin. Indirect fluorescent antibody labelling of ghost myofibrils shows that desmin, α -actinin and actin are all present at the Z-disk level. Similar labelling of Z disk sheets reveals that α -actinin is located as expected in the Z-disks whereas desmin labels the areas between the Z-disks forming an interconnecting network across the fibre. Antibody to actin seems to label the whole Z-disk sheet.

Previous observations of Lazarides and Granger (*Proc. natn. Acad. Sci. U.S.A.* 75, 3683; 1978) using a fluorescent dye to mark the hydrophobic,

Pauline Bennett is in the MRC Cell Biophysics Unit, King's College, London.

and hence presumably the membrane positions in glycerol-extracted fibres showed substantial fluorescence at the Z-line level and around the Z-disks in Z-disk sheets. The location of desmin thus seems to coincide with that of the membrane, probably the T-tubule system.

Since the resolution of the light microscope does not allow the precise position of desmin to be determined, Lazarides and his colleagues suggest a number of possible interpretations of the data. First the desmin may be involved in mediating the adhesion of the T-tubule to neighbouring Z-disks. Alternatively, desmin might be associated with direct fibrous links between Z-disks which are independent of the T-tubules. The first possibility offers a good explanation for the precise location of the T-tubules in the muscle cell and finds support in the general observation of the authors that desmin is present where membranes and actin appear to be associated such as in the intercalating disk in heart muscle. A test of this hypothesis would be to study the distribution of desmin in mammalian skeletal muscle. Here the T-tubules are located at the junction of the A and I-bands, not at the Z-disk level as in avian muscle, which should lead to a different antibody staining pattern. Unfortunately Lazarides and Balzer (*Cell* 14, 429; 1978) have shown that their antibody is specific only for avian muscle, but they have some evidence from two-dimensional gel electrophoresis that a similar protein is present in mammalian muscle.

The alternative proposal that desmin forms direct links between Z-disks is based in addition on the observations of filaments lying between Z-disks in ghost fibres. However, these are considerably longer than the distance between myofibrils in intact muscle. The evidence that these filaments are composed of desmin is indirect. Lazarides and his colleagues consider that desmin is the same as the protein, skeletin, isolated by Small and Sobieszek (*J. Cell Sci.* 23, 243; 1977) from chicken smooth muscle where it is the major component of the 100 Å filaments. There is a possibility that these two proteins are not identical. The extraction procedures used by the two groups are different, as is, slightly, the molecular weight attributed to the proteins. Furthermore it is unusual to find a protein which does not have a similar morphology in very different cell types and no 100 Å filaments have been detected in skeletal muscle, although a few could easily go unnoticed. If these objections are not valid can I broadcast a plea for the groups involved to get together to decide on a common nomenclature. In

view of the, at present, confused state of the field of 100 Å filaments, this is an important point to clarify.

Whatever the state of desmin in the muscle it is clear that in this protein we now have a handle with which to tackle the problem of how the transverse order is maintained in the striated muscle cell and can further hope to discover how it is related to the putative longitudinal cytoskeleton.

Enzyme therapy in genetic diseases

from Gregory Gregoriadis and Michael F. Dean

THERE are numerous genetic disorders in which, because of a partial or total absence of a specific enzyme, substrates normally metabolised by the enzyme accumulate intracellularly or extracellularly. This leads to profound defects in the function of the patient's tissues and in many instances to severe incapacitation or early death. Treatment for most of these disorders has been mainly symptomatic and, in a few cases, dietary. However, as knowledge of the molecular mechanism of these diseases progresses, more sophisticated attempts at therapy can be undertaken. Since therapy by genetic manipulations is only a distant possibility, efforts have concentrated on more immediate solutions, namely reduction of the substrate load by restoration of enzyme activity or other methods.

Enzyme therapy has recently gained a new impetus as a result of the advances in methodology discussed by D. Robinson (Queen Elizabeth College, London) which have provided us with bulk quantities of enzymes from human tissues, especially placenta (for example α -galactosidase, C. C. Sweeley, Michigan State University, East Lansing; glucocerebrosidase, G. L. Dale, City of Hope Medical Center, Duarte) and in the possible use of bacteria for the synthesis of biologically active proteins (L. Villa-Komaroff, University of Massachusetts Medical School, Worcester; R. D. Schmickel, University of Michigan, Ann Arbor). Another reason is the discovery that many enzymes possess recognition markers which facilitate their very rapid specific uptake by cells (E. Neufeld, National Institutes of Health, Bethesda). There is, for instance, a

phosphomannosyl recognition marker on several lysosomal hydrolases mediating their uptake by fibroblasts (W. Sly, Washington University School of Medicine, St. Louis), a fucosyl marker on glycoproteins recognised by hepatocytes (R. L. Hill, Duke University Medical Center, Durham) and an as yet uncharacterised group on β -hexosaminidase A which seems to promote binding of the enzyme by brain synaptic plasma membranes (J. W. Kusiak, National Institutes of Health). In the case of human β -hexosaminidase of which hepatic uptake in cats is due to a receptor recognising N-acetylglucosaminyl and mannosyl residues on the enzyme, unwanted participation of the liver can be suppressed (in favour of other tissues) by substances which compete for similar binding sites. This allows the enzyme to circulate longer and by increasing blood brain barrier permeability after exposing animals to hyperbaric oxygen, enzyme can thus reach nervous tissue (M. C. Rattazzi, State University of New York at Buffalo). Accessibility of enzymes to brain is also achieved by hypertonic shock using arabinose or mannitol which shrink the cells lining the vascular endothelium (J. A. Barranger, National Institutes of Health).

Difficulties in controlling the fate and effect of enzymes *in vivo* could be overcome by the use of carriers (naturally occurring or synthetic) which may, in various ways, improve enzyme distribution and action. Disappointingly, in type I Gaucher's disease in which glucocerebroside storage results in hepatomegaly (and splenomegaly), multiple injections of human glucocerebrosidase: β -glucosidase entrapped in γ -globulin-coated erythrocytes (E. Beutler, Scripps Clinic and Research Foundation, La Jolla) or in liposomes (G. Gregoriadis, Clinical Research Centre, Harrow) failed to reduce appreciably the size of the liver even though this tissue is the principal site for localisation of the carrier-associated enzyme. Nonetheless, after 3 years of treatment with liposomal enzyme there was some clinical improvement of the patient. Fortunately, neither of the carriers affected blood clotting factors or α -macroglobulin (liposomes). Some clinical improvement was also seen in Gaucher's disease patients injected with the free enzyme but a substantial reduction of hepatic glucocerebrosidase (also shown in liver biopsies exposed to the enzyme *in vitro*) was not paralleled by a reduction in the organ's size (R. O. Brady, National Institutes of Health). It may be that long-term therapy is required for the reversal of the process of organ enlargement and, at any rate, the amount of enzyme given should be sufficiently high to at least prevent further glycolipid storage.

The 2nd International Symposium on Enzyme Therapy of Genetic Diseases was held at Hilton Head Island, South Carolina on 4-7 March and was organised by R. J. Denick under the sponsorship of the National Foundation-March of Dimes and the Mount Sinai School of Medicine.

Enzyme therapy by transplanting hepatic or bone marrow cells in immunosuppressed animals with model diseases, was partly successful (D Sutherland, University of Minnesota, Minneapolis) although, with the exception of acute hepatic failure (where only temporary action is required), rejection remains a formidable obstacle for use in man. There has been, however, some success with bone marrow transplants in immune deficiency disease. Furthermore, transplants of HLA-identical fibroblasts increased levels of the relevant enzymes in patients with Hurler's, Hunter's and Sanfilippo type A diseases for up to several years and there was no evidence of graft rejection (M. F. Dean, Kennedy Institute of Rheumatology, London; D. Gibbs, Clinical Research Centre, Harrow). A more hopeful alternative would, of course, be transplantation of cells after they have been corrected for the malfunctioning or missing gene by one of the available methods.

A subtle and perhaps more efficient method of restoring enzyme activity in a large group of disorders is the administration of massive doses of specific vitamins (see review by C. R. Scriver, in *Treatment of Inborn Errors of Metabolism* (eds Seakins, Saunders & Toothill) 127, Churchill Livingstone, Edinburgh and London, 1973) which through a variety of mechanisms (for example the coenzyme may form part of the active site of the enzyme, affect apoenzyme synthesis and degradation or influence the specific activity of the enzyme by altering its conformation), result in beneficial biochemical and clinical changes (G. E. Gaull, Mount Sinai School of Medicine, New York). Much of the understanding of vitamin action has come from work with vitamin B and aspartate- β -decarboxylase (A. Meister, Cornell University Medical College, New York). A similar (but limited to mannosidosis) approach may be ingestion of Zn which can activate the partially missing α -mannosidase (G. A. Grabowski, University of Minnesota, Minneapolis). The almost certain effects of Zn on the absorption and metabolism of other trace metals could, however, prove unacceptable. In yet another approach advantage is taken of the equilibrium thought to exist between the various pools of substrate in the body. For instance, plasmapheresis coupled with a phytanic acid-poor diet lowered serum phytanic acid considerably and slightly improved muscular strength in a patient with Refsum's disease. Plasmapheresis alone reduced tri-

hexosylceramide levels to normal for a several day period in a patient with Fabry's disease (H. W. Moser, The John F. Kennedy Institute, Baltimore). The latter finding was also observed after repeated injections of plasma α -galactosidase A isozyme in two brothers with the same disease (R. J. Desnick, Mount Sinai School of Medicine).

Although some of these attempts at therapy have already benefited patients and some may have saved lives, most of the clinical trials were not preceded by animal experimentation, because animal models of human genetic diseases are extremely rare. The setting-up of such models is essential if therapy is to become more effective. An interesting example of a mouse with multiple lysosomal enzyme

deficiencies was demonstrated by P. Pentchev (National Institutes of Health). Even so, direct clinical trials are often a necessity. For instance, work with animal models is of little use in determining the likely immunogenicity of enzymes or cells prepared from human sources or whether cells from seemingly healthy donors may be contaminated with viruses, infectious viral components or with malignant cells. Some of these contaminants are impossible to measure or even anticipate and recipients, especially if immunosuppressed, may therefore be at risk. Similarly, artificial carriers such as liposomes, although controllable in terms of infectious contaminants, may exaggerate antigenicity through an adjuvant action

A hundred years ago

In the interests of British science we have refrained now for some time from referring to the evil days which have fallen upon one of the most reputable of our learned societies. The time, however, has now come when silence is impossible. At the meeting of the Royal Astronomical Council yesterday, the Astronomer-Royal, in consequence of the recent action of the Council—an action inevitable when the present constitution of that body is considered—resigned his seat at the board. We cannot too much regret that this Society, the traditions of which are second to none in Europe, should have been utilised for some years past by an advertising clique who have everything to gain by their connection with a body of honourable students of science. The withdrawal of men long known for their astronomical work from the Council commenced some time since. It has now culminated in the resignation of the Astronomer-Royal, and we are informed that other resignations are to follow, indeed, a man of scientific repute risks somewhat in being found amongst the Councillors. Surely the Fellows of the Royal Astronomical Society of London are strong enough to remedy such a state of things as this.

At a recent meeting of the Medical Society of Berlin Prof. Virchow gave (by previous request) his views on the subject of the Plague of Astrakhan.

At the beginning of most pestilential epidemics a Committee of doctors has generally declared that it was not the plague. They pronounced it petechial typhus. This was the case immediately before the outbreak of the plague at Rescht, when the disease had been long confined in Kurdistan and Mesopotamia. M. Tholozan was the first to say it was plague, and that the case was that, not of a great epidemic, but of a latent disease, spreading slowly and attacking only a few. It is indubitable that we have there a true centre,

whence the disease gradually spread, and I do not see why we should go to India, where the disease has not prevailed for many years past. Proceeding logically, we shall accept this course. From Kurdistan and Mesopotamia to Persia and on to beyond the Caspian. Even if the present cases on the other side of the Caspian were accompanied by pneumorrhagia, I would not hesitate to say they belonged to the plague proper, and that the disease is the same as that in Mesopotamia. The symptoms are very different from those of petechial typhus, the disease which the Turkish doctors affirmed. If near Salonichi (Xanthi) there be really petechial typhus accompanied by *Metastasis bubonica*, I fear it is the plague. It remains to keep our eyes open and see what happens after the return of the Russian army from the infected country (an occurrence which may well rouse grave apprehensions).

What has been done for our protection is little apt to tranquillise us. A blockade comprising all the frontier as well as the coast, from the Baltic to the Black Sea, seems to me illusory.

One example of severe quarantine has occurred in this century in the case of the plague at Noja, in Bari (Kingdom of Naples), in 1815. Trenches were dug, and three cordons of sentinels were formed (the third round the entire province), with orders to kill whoever tried to break the blockade and did not stop at the first summons; and some individuals were actually killed. But I cannot think an entire country is able to protect itself thus. Examination of passports would be excellent if those who deliver passports and certificates of health were angels. But the Russian functionaries are men, and think like men. The impossibility of always getting true certificates of origin has been seen in the case of the cattle plague. I consider, however, that pressure should be exerted on Russia to form a blockade of the infected districts. And especially it should be seen to, that the returning Russian army does not bring any pestilential germs, with it. As to restrictions on communications by land, the greatest of these are ineffectual for the end desired.

The anthropic principle and the structure of the physical world

B. J. Carr* & M. J. Rees

Institute of Astronomy, Madingley Road, Cambridge, UK

The basic features of galaxies, stars, planets and the everyday world are essentially determined by a few microphysical constants and by the effects of gravitation. Many interrelations between different scales that at first sight seem surprising are straightforward consequences of simple physical arguments. But several aspects of our Universe—some of which seem to be prerequisites for the evolution of any form of life—depend rather delicately on apparent ‘coincidences’ among the physical constants.

THE structure of the physical world is manifested on many different scales, ranging from the Universe on the largest scale, down through galaxies, stars and planets, to living creatures, cells and atoms. Only objects such as quarks and leptons may be devoid of further substructure. Each level of structure requires for its description and explanation a different branch of physical theory, so it is not always appreciated how intimately they are related. We will show here that most natural scales are determined (to an order of magnitude) by just a few physical constants. In particular, the mass scale and length scale (in units of the proton mass m_p and the Bohr radius a_0) of all structures down to the atom can be expressed in terms of the electromagnetic fine structure constant, $\alpha = e^2/\hbar c$, the gravitational fine structure constant, $\alpha_G = Gm_p^2/\hbar c$ and the electron-to-proton mass ratio, m_e/m_p . The quantity m_e/m_p is related to α due to a coincidence in nuclear physics. These dependences are indicated explicitly in Fig. 1.

There are several amusing relationships between the different scales. For example, the size of a planet is the geometric mean of the size of the Universe and the size of an atom; the mass of man is the geometric mean of the mass of a planet and the mass of a proton. Such relationships, as well as the basic dependences on α and α_G from which they derive, might be regarded as coincidences if one did not appreciate that they can be deduced from known physical theory.

However, one of the scales in Fig. 1, that associated with the Universe, cannot be explained directly from known physics: it is apparently a coincidence that the present age of the Universe is of the order of α_G^{-1} times the electron timescale $\hbar/m_e c^2$. This led Dirac¹ to conjecture that G decreases with time as t^{-1} , so that the two timescales are always comparable. A more metaphysical explanation by Dicke² is that conditions are propitious for the existence of observers only when $t \approx \alpha_G^{-1} \hbar/m_e c^2$, so that this ‘coincidence’ should be of no surprise. This line of argument, which is discussed later, appeals to the ‘anthropic’ principle³. Later we shall also mention other features of the material world that seem sensitive to apparent coincidences among physical constants.

To describe structures on scales smaller than the atom one needs extra constants: in particular, the weak and strong inter-

action coupling constants g_w and f . It might be assumed that these are independent of α and α_G but there are some ‘anthropic’ interconnections between these numbers. For example, the condition that neutrinos can blow off the envelope of a star in its supernova phase will be shown to be, roughly speaking, $\alpha_G \sim \alpha_w^4$ where $\alpha_w = g_w^2 c/\hbar^3$ is the weak fine structure constant. Supernovae are essential if the heavy elements which are (presumably) necessary for life are to spread from their production sites throughout space. The same relationship between α_G and α_w explains why the cosmological helium production is $\sim 25\%$ by mass. If α_w were slightly smaller or larger, the helium production would be either 100% (in which case there would never be any water, perhaps another prerequisite for life) or 0% (in which case stellar evolution would be rather different). Finally there are coincidences between f and α and the elementary particle mass ratios which may be necessary for chemistry. There may be enough independent anthropic constraints to pin down the order of magnitude of α and α_G , and also that of α_w and f . Such considerations do not provide a real physical explanation, but they may indicate why these fundamental ratios are found to have their measured values.

One other important parameter in the Universe is the entropy per baryon or, equivalently, the photon-to-baryon ratio $\mathcal{S}$, which is of the order of 10^8 . The value of $\mathcal{S}$ has no explanation within the conventional hot big bang theory but it is also associated with a coincidence: if $\mathcal{S} \sim 10^8$, the matter and radiation densities are comparable at the time they thermally decouple. Although the anthropic principle does not seem to require a specific value for $\mathcal{S}$, it does require an upper limit on $\mathcal{S}$ of order $\alpha_G^{-1/4}$; otherwise, galaxies and stars would be unable to form through gravitational condensation. In fact, there are several schemes which suggest how an entropy parameter of the order of $\alpha_G^{-1/4}$ could be generated naturally.

Scales of structure in nature

We now present some simple arguments for the mass and length scales shown in Fig. 1. These are mostly straightforward consequences of simple physics. Many have been given before, but it is useful to bring them together. All our discussions will be based on order of magnitude arguments, so equations will be of the ‘ $\sim$ ’ rather than ‘ $=$ ’ kind, factors like π being neglected.

*Present address: California Institute of Technology, Pasadena, California 91109.

Protons: the size of a proton is taken to be the Compton wavelength associated with its rest mass:

$$r_p \sim \frac{\hbar}{m_p c} \sim 10^{-13} \text{ cm} \quad (1)$$

This is roughly the range of the strong interaction. Associated with r_p is the timescale $t_p = r_p/c \sim 10^{-23}$ s, the typical lifetime of a strong interaction resonance. By analogy with equation (1), the size or localisability of an electron is sometimes referred to as

$$r_e \sim \frac{\hbar}{m_e c} \sim 10^{-10} \text{ cm} \quad (2)$$

and we can define a corresponding electron timescale $t_e = r_e/c \sim 10^{-20}$ s.

Atoms: for a hydrogen atom the radius of the lowest energy electron orbit is

$$a_0 \sim \frac{\hbar^2}{m_e e^2} \sim 10^{-8} \text{ cm} \sim 1 \text{ Bohr} \quad (3)$$

and the associated energy is

$$E_0 \sim \frac{e^4 m_e}{\hbar^2} \sim 10 \text{ eV} \sim 1 \text{ Rydberg} \quad (4)$$

As one considers atoms of greater atomic number Z , the binding energy increases roughly as Z^2 and the radius of the inner shell electron orbit decreases roughly as Z^{-1} . However, the radius of the outer shell electron orbit remains of the order of a_0 , so all atoms have about the same size. If one introduces the fine structure constant

$$\alpha = \frac{e^2}{\hbar c} \sim \frac{1}{137} \quad (5)$$

one can write a_0 and E_0 as

$$a_0 \sim \alpha^{-2} \left(\frac{e^2}{m_e c^2} \right) \quad E_0 \sim \alpha^2 m_e c^2 \quad (6)$$

The quantity $(e^2/m_e c^2)$ is the 'classical' radius of the electron $\sim 10^{-13}$ cm. Atomic masses span a range from 1 to roughly α^{-1} times m_p . The nuclei of atoms with atomic number exceeding α^{-1} have so much electrostatic binding energy that they are unstable to electron-positron pair production. In practice, the instability to fissioning comes in at a somewhat smaller atomic number.

The Planck scales: the only quantities of dimensions mass and length which can be constructed from G , $\hbar$ and c are the Planck scales:

$$M_{\text{Pl}} \sim \left(\frac{G}{\hbar c} \right)^{-1/2} \sim 10^{-5} \text{ g} \quad R_{\text{Pl}} \sim \left(\frac{G}{\hbar c^3} \right)^{1/2} \sim 10^{-33} \text{ cm} \quad (7)$$

By introducing the gravitational fine structure constant,

$$\alpha_G = \frac{G m_p^2}{\hbar c} \sim 5 \times 10^{-39} \quad (8)$$

these scales can be expressed as

$$M_{\text{Pl}} \sim \alpha_G^{-1/2} m_p \quad R_{\text{Pl}} \sim \alpha_G^{1/2} r_p \quad (9)$$

So M_{Pl} is much larger than m_p but R_{Pl} is much smaller than r_p . The Planck length is the scale on which quantum gravitational fluctuations in the metric become of the order of unity, so the concept of space breaks down at such small scales. M_{Pl} can be interpreted as the mass of a black hole of radius R_{Pl} . Space may be thought of as being filled with virtual black holes of this size. Such 'instantons' have an important role in quantum gravity theory.

Black holes: the radius of a spherically symmetrical black hole of mass M is

$$R = \frac{2GM}{c^2} \sim \alpha_G \left(\frac{M}{m_p} \right) r_p \quad (10)$$

Fig. 1 The mass and length scales of various natural structures expressed in terms of the electromagnetic and gravitational fine structure constants, α and α_G . Some of these scales also depend on the electron-to-proton mass ratio, but this we have eliminated using $m_e/m_p \sim 10\alpha^2$. The asteroid scale also depends on the molecular weight A of rocky material. All these scales can be deduced directly from known physics except for the mass and length scale of the Universe, which depends on the age of the Universe being α_G^{-1} times the electron timescale $\hbar/m_e c^2$. Also shown are the atomic density line, the nuclear density line, the black hole density line and the 'quantum line' corresponding to the Compton wavelength. Most characteristic scales depend on simple powers of α_G ; the wide span of so many orders of magnitudes is a consequence of the huge numerical value of α_G^{-1} , which reflects the weakness of gravity on the microscopic scale.

This is the radius of the event horizon, the region from within which nothing can ever escape (at least, classically). Black holes larger than $1 M_\odot$ may form from the collapse of stars or dense star clusters. Smaller holes require much greater compression for their formation than could arise in the present epoch, but they might have been produced in the first instants after the big bang when the required compression could have occurred naturally. Such 'primordial' black holes could have any mass down to the Planck mass. In fact, Hawking⁴ has shown that small black holes are not black at all; because of quantum effects they emit particles like a black body of temperature given by

$$k\theta \sim \frac{\hbar c^3}{GM} \sim \alpha_G^{-1} \left(\frac{M}{m_p} \right)^{-1} m_p c^2 \quad (11)$$

This means that a hole of mass M will evaporate completely in a time

$$t_{\text{evap}} \sim \alpha_G^2 \left(\frac{M}{m_p} \right)^3 t_p (N(\theta))^{-1} \quad (12)$$

$N(\theta)$ is the number of species contributing to the thermal radiation; for $k\theta \ll m_e c^2$ these include only photons, neutrinos and gravitons; but at higher temperatures other species may contribute. The evaporation terminates in a violent explosion. For a solar mass hole, this quantum radiance is negligible: θ is

only 10^{-7} K and $t_{\text{evap}} \sim 10^{64}$ yr. But for small holes it is very important. A Planck mass hole has a temperature of 10^{32} K and only survives for a time $\sim R_{\text{Pl}}/c \sim 10^{-43}$ s. Those holes which are terminating their evaporation in the present epoch are particularly interesting. As the age of the Universe is $t_0 \sim \alpha_G^{-1} t_e$, the mass of such holes would be

$$M_h \sim \alpha_G^{-2/3} \left(\frac{t_0}{t_p} \right)^{1/3} m_p \sim \alpha_G^{-1} m_p \sim 10^{15} \text{ g} \quad (13)$$

and, from equation (10), their radius would be r_p . (The corresponding temperature is ~ 10 Mev: low enough to eliminate any uncertainty in $N(\theta)$ due to species of exotic heavy particles.)

Stars: Jordan⁵ first noted that the Sun has a mass of about $\alpha_G^{-3/2}$ times the proton mass; most stars have a mass in the range 0.1–10 times this. Jordan constructed an elaborate cosmological theory to explain this ‘coincidence’, but we will now see why stars are expected to lie in this mass range^{6,7}. The virial theorem implies that the gravitational binding energy of a star must be of the order of its internal energy. Its internal energy comprises the kinetic energy per particle (radiation pressure being assumed negligible for the moment) and the degeneracy energy per particle. The degeneracy energy will be associated primarily with the Fermi-momentum of the free electrons, $p \sim \hbar/d$, where d is their average separation. Provided the electrons are non-relativistic, the degeneracy energy is $p^2/2m_e$, so the virial theorem implies

$$kT + \frac{\hbar^2}{2m_e d^2} \sim \frac{GMm_p}{R} \sim \left(\frac{N}{N_0} \right)^{2/3} \frac{\hbar c}{d} \quad (14)$$

Here N is the number of protons in the star, $N_0 \equiv \alpha_G^{-3/2}$, and $R \sim N^{1/3} d$ is its radius. As a cloud collapses under gravity, equation (14) implies that, for large d , T increases as d^{-1} . For small d , however, T will reach a maximum

$$kT_{\text{max}} \sim \left(\frac{N}{N_0} \right)^{4/3} m_e c^2 \quad (15)$$

and then decrease, reaching zero when d is

$$d_{\text{min}} \sim \left(\frac{N}{N_0} \right)^{-2/3} r_e \quad (16)$$

A collapsing cloud becomes a star only if T_{max} is high enough for nuclear reactions to occur, that is $kT_{\text{max}} > qm_e c^2$ where q depends on the strong and electromagnetic interaction constants and is $\sim 10^{-2}$. From equation (15), one therefore needs $N > 0.1 N_0$. Once a star has ignited, further collapse will be postponed until it has burnt all its nuclear fuel. An upper limit to the mass of a star derives from the requirement that it should not be radiation-pressure dominated. Such a star would be unstable to pulsations which would probably result in its disruption. Using the virial theorem (that is, equation (14) with the degeneracy term assumed negligible) to relate a star's temperature T to its mass $M \sim Nm_p$ and radius R , the ratio of radiation pressure to matter pressure can be shown to be

$$\frac{P_{\text{rad}}}{P_{\text{mat}}} \sim \frac{aT^4 R^3}{NkT} \sim \left(\frac{N}{N_0} \right)^2 \quad (17)$$

so the upper limit to the mass of a star is also $\sim N_0 m_p$. A more careful calculation shows that there is an extra numerical factor of the order of 10, so one expects all main-sequence stars to lie in the range $0.1 \leq N/N_0 \leq 10$ observed.

In other words, only assemblages of 10^{56} – 10^{58} particles can turn into stable main sequence stars with H-burning cores. Less massive bodies held together by their own gravity can be supported by electron ‘exclusion principle’ forces at lower temperatures (they would not get hot enough to undergo nuclear fusion unless squeezed by an external pressure); heavier bodies are fragile and unstable owing to radiation pressure effects.

The M – R relationship for main-sequence stars is shown in Fig. 2, and can be deduced from the virial theorem and a knowledge of T , the central temperature. T adjusts itself so that

the nuclear energy generation rate balances the luminosity, the radiant energy content divided by the photon leakage time,

$$L \simeq acT^4 R^4 / \kappa M \quad (18)$$

where κ is the opacity. The appropriate κ decreases as M increases (electron scattering being the dominant opacity for upper main-sequence stars) but the energy generation increases so steeply with T that M/R depends only weakly on M .

White dwarfs and neutron stars: when a star has burnt all its nuclear fuel, it will continue to collapse according to equation (14) and, providing it is not too large, it will end up as a cold electron-degeneracy supported ‘white dwarf’ with the radius $R \propto M^{-1/3}$ indicated by equation (16). However, when M gets so large that $kT_{\text{max}} \sim m_e c^2$, the electrons will end up relativistic, with the degeneracy energy being pc rather than $p^2/2m_e$. Thus the degeneracy term in equation (14) acts as d^{-1} instead of d^{-2} , and consequently there is no $T=0$ equilibrium state. From equation (15) this happens if M exceeds the mass

$$M_c \sim \alpha_G^{-3/2} m_p \sim 1 M_\odot \quad (19)$$

which characterises stars in general. A more precise expression for this critical value of M (Chandrasekhar mass) is $5.6 \mu^2 M_\odot$ where μ is the number of free electrons per nucleon⁸. For a star which has burned all the way up to iron, $\mu \approx 1/2$ and the limiting Chandrasekhar mass, taking into account the onset of inverse β -decay when electrons get relativistic, is $\sim 1.25 M_\odot$. Note that the white dwarf line in Fig. 2 meets the main-sequence line on the nuclear ignition ($T \sim 10^7$ K) isotherm. Stars bigger than M_c will collapse beyond the white dwarf density but may manage to shed some of their mass in a supernova explosion. The remnant core will comprise mainly neutrons, the electrons having been squeezed onto the protons through $p + e^- \rightarrow n + \nu$, and this core,

Fig. 2 An enlargement of part of Fig. 1. All solid planets lie on the atomic density line and all main sequence stars lie in the narrow mass range 0.1–10 times $\alpha_G^{-3/2} m_p$ (shaded). Regions with mass below this range would never get hot enough to ignite their nuclear fuel; regions with mass above this range would be radiation pressure dominated and consequently unstable. General relativistic instabilities are important for masses $\gg M_c$ (not shown). The precise form of the main-sequence band depends on the opacity and the nuclear reaction rate. All stars smaller than the Chandrasekhar mass ($\sim 1.4 M_\odot$) must eventually end up on the electron-degeneracy-supported white dwarf line. Stars bigger than this either shed some of their mass in a supernova explosion and end up as a neutron star or collapse to a black hole. Objects on the dotted line which bridges the white dwarf and nuclear density lines are unstable. Also shown are the ($T \sim 10^7$ K) nuclear ignition isotherm and the ($T \sim 10^4$ K) ionisation isotherm.

if small enough, may be supported by the neutron-degeneracy pressure. The limiting mass for a neutron star is more difficult to calculate than that for a white dwarf because of strong interaction effects and because, from equation (15), with $m_e \rightarrow m_p$, the particles which dominate the neutron star's mass are relativistic. The maximum mass is still of the order of $1 M_\odot$, however, and a neutron star bigger than this must collapse to a black hole. The maximum mass lies close to the intercept of the black hole line, given by equation (10), and the nuclear density line $\rho \sim m_p/r_p^3$. The intricacies of the line which bridges the white dwarf and neutron star regimes in Fig. 2 reflect the effects of gradual neutronisation and strong interactions. Stars on this bridge would be unstable and so are not of physical interest.

The above order-of-magnitude arguments show why the effects of radiation pressure, and relativistic degeneracy both become important for masses $\geq \alpha_G^{-3/2} m_p$. (Note also that general relativity is unimportant for white dwarfs because the binding energy per unit mass is only $\sim (m_e/m_p)$ of c^2 at the Chandrasekhar limit.)

Planets and asteroids: the above analysis applies only to objects where the thermal energy kT and/or the degeneracy energy per electron exceeds the ionisation energy $\sim \alpha^2 m_e c^2$. If T is too small, the object will be solid or liquid rather than gaseous, in which case its structure is determined by the balance of degeneracy and chemical bonds rather than degeneracy and gravity. Since the degeneracy and electrostatic binding energy per particle are $\hbar^2 n^{2/3} m_e^{-1}$ and $e^2 n^{1/3}$, the density of any solid or liquid is of the order of the atomic density

$$\rho_0 \sim e^6 m_e^3 m_p \hbar^{-6} \sim \frac{m_p}{a_0^3} \sim 1 \text{ g cm}^{-3} \quad (20)$$

From equation (16), the atomic density line meets the white dwarf line ($d_{\min} \sim a_0$) at a mass and radius

$$\begin{aligned} M &\sim \left(\frac{\alpha}{\alpha_G}\right)^{3/2} m_p \sim \alpha^{3/2} M_e \sim 10^{30} \text{ g} \\ R &\sim \left(\frac{\alpha}{\alpha_G}\right)^{1/2} a_0 \sim 10^{10} \text{ cm} \end{aligned} \quad (21)$$

This point in Fig. 2 also lies on the $kT \sim \alpha^2 m_e c^2$ isotherm. Equation (21) characterises the maximum size of a planet and is of the order of the size of Jupiter. The central pressure of a self-gravitating body more massive than this can be balanced by degeneracy pressure only if the electrons are crushed closer together than in an ordinary solid. A lower limit for the size of a (solid) planet can be specified if the planet is reasonably round—that it be bigger than its own mountains. The maximum size of a mountain can be found from the following argument⁷. A mountain of height h must not provide so much pressure on the planet's surface that it liquifies its base. The condition for this is easily shown to be

$$h < h_{\max} \sim \frac{E_{\text{liq}}}{A m_p g} \quad (22)$$

where A is the molecular weight of the planetary material, g is the surface gravity and E_{liq} is the liquefaction energy per molecule. The binding energy of a solid is about 0.1 Rydberg per molecule and E_{liq} is about a tenth of this (as only the directionality of the bonds is broken in liquefaction), so

$$E_{\text{liq}} \sim \beta \alpha^2 m_e c^2 \quad (\beta \sim 10^{-2}) \quad (23)$$

For the Earth, $g \sim 10^3 \text{ cm s}^{-2}$ and equation (22) implies a maximum height of the order of 10 km. In general one has

$$g \sim \frac{GM}{R^2} \sim G \left(\frac{M}{m_p}\right)^{1/3} A^{2/3} (y a_0)^{-2} m_p \quad (24)$$

where $y a_0$ is the molecular size of the planetary material. (A solid terrestrial-type planet is mostly SiO_2 and iron, for which $A \sim 60$ and $y \sim 4$.) Equations (22–24) thus imply

$$h_{\max} \sim (\beta y^2) \left(\frac{\alpha}{\alpha_G}\right) \left(\frac{M}{m_p}\right)^{-1/3} A^{-5/3} \quad (25)$$

This is less than the radius of the planet, $R \sim y a_0 (M/A m_p)^{1/3}$, provided M and R exceed

$$M \sim (y\beta)^{3/2} A^{-2} \left(\frac{\alpha}{\alpha_G}\right)^{3/2} m_p, \quad R \sim A^{-1} \left(\frac{\alpha}{\alpha_G}\right)^{1/2} a_0 (y^3 \beta)^{1/2} \quad (26)$$

which is thus the maximum size of an irregularly shaped 'asteroid'. The value of A is constrained by the requirement that solid planets must be made of material whose atomic number is sufficiently high that it is not vaporised by the high temperatures attained during the formation of the Solar System.

'Habitable' planets: the mass range of habitable planets can be narrowed down still further if an atmosphere and an appropriate surface temperature are required⁹. The optimum temperature for organisms is $T \sim \epsilon/k$, where $\epsilon \sim 10^{-3}$ Rydberg is the typical energy released in relevant reactions involving complex molecules: were T much larger, the molecules would be disrupted; were it much smaller, biological processes would require an exponentially long timescale. If an atmosphere composed of gas heavier than hydrogen were necessary for life, then the thermal velocity of hydrogen at this temperature should be slightly greater than the escape velocity from the planet, which implies

$$\frac{GMm_p}{R} \sim \epsilon \alpha^2 m_e c^2 \quad (27)$$

With the relationship $M/R^3 \sim A m_p / y^3 a_0^3 \sim m_p / a_0^3$, this implies that a life-supporting planet must have a mass

$$M \sim \epsilon^{3/2} \left(\frac{\alpha}{\alpha_G}\right)^{3/2} m_p \quad (28)$$

Only a small fraction of planets in the mass range permitted by equations (21) and (26) would satisfy this criterion.

Press⁹ has used this line of argument to set an upper limit to the size of living creatures on the basis that they must not 'break' when they fall: the energy released by a body of mass M_m in falling from height h_m on a planet whose surface gravity is given by equation (28) must be insufficient to break the molecular bonds on an area h_m^2 . This yields an upper limit

$$M_m h_m \left(\frac{GM}{R^2}\right) \leq \left(\frac{M_m}{m_p}\right)^{2/3} \epsilon \alpha^2 m_e c^2 \quad (29)$$

Substituting for M with equation (28) and assuming atomic density, this implies

$$h_m \sim \epsilon^{1/4} \left(\frac{\alpha}{\alpha_G}\right)^{1/4} a_0 \sim \left(\frac{\epsilon}{0.001}\right)^{1/4} \text{ cm} \quad (30)$$

with only a weak dependence on ϵ . If one assumes that the surface stresses are distributed along faults as wide as a polymer, the estimate for h_m is increased by a factor of 100. (In fact, equation (30) is more appropriate as the estimate for the size of a water droplet, which can be derived from a similar argument⁷.) Allowing for the factor of 100, the mass associated with h_m is

$$M_m \sim 10^3 \left(\frac{\alpha}{\alpha_G}\right)^{3/4} m_p \sim 10^5 \text{ g} \quad (31)$$

which is roughly the mass of a man. We plot this mass in Fig. 1, although its value is very uncertain (and is in any case irrelevant to swimming organisms); note its dependence on $\alpha_G^{-3/4}$.

The Universe: in the simplest Friedmann cosmological model, the age of the Universe t_0 is of the order of H_0^{-1} where H_0 is the Hubble parameter. (This relation fails only if the Universe is closed and near its maximum expansion.) Since $H_0 \sim 50 \text{ km s}^{-1} \text{ Mpc}^{-1}$, this implies $t_0 \sim 10^{10} \text{ yr}$, a conclusion which is supported by several independent arguments. The associated horizon size (the distance travelled by light since the beginning of the Universe) satisfies the approximate relationship

$$ct_0 \sim \alpha_G^{-1} \left(\frac{\hbar}{m_e c}\right) \sim \left(\frac{\alpha}{\alpha_G}\right) a_0 \quad (32)$$

In other words the ratio of the size of the observable Universe to the size of an atom is comparable with the ratio of the electrical (or nuclear) and gravitational forces between elementary particles. There is no explanation for this well known coincidence within conventional physics, but Dirac¹ has conjectured that α_G is always given by

$$\alpha_G \sim \frac{\hbar}{m_e c^2 t} \sim \left(\frac{t}{t_0}\right)^{-1} \quad (33)$$

Assuming that $\hbar$, c , and m_e are constant in time, this requires that G decreases as t^{-1} , so Dirac invokes equation (32) as the basis for a new cosmology. Such a variation of G may be inconsistent with observation.

An alternative 'anthropic' explanation for equation (32) was first suggested by Dicke². As life presumably requires elements heavier than hydrogen and helium and such elements can only be produced and spread throughout the Universe by supernovae, Dicke argued that any 'cognisable' Universe would be one in which some stars have already completed their main-sequence evolution. The luminosity of a star whose opacity is dominated by electron scattering (as applies for large stars) is $\sim (P_{\text{rad}}/p)L_E$; (P_{rad}/p) is given in terms of M by equation (17) and L_E is the Eddington luminosity, $4\pi GMm_p c/\sigma_T$, where $\sigma_T = \alpha^2 r_e^2$ is the Thomson cross-section. A characteristic timescale¹⁰ is that over which an object of luminosity L_E would radiate away its entire rest mass:

$$t_* = \frac{c\sigma_T}{4\pi GMm_p} = \left(\frac{\alpha^2}{\alpha_G}\right) \left(\frac{m_p}{m_e}\right)^2 t_p \quad (34)$$

and this timescale involves the 'large number' α_G^{-1} explicitly. If $\eta \ll 10^{-2}$ is the fraction of a star's rest mass that can be released through nuclear burning, the main sequence lifetime is thus

$$t_{\text{MS}} \sim \eta \left(\frac{P_{\text{rad}}}{p}\right)^{-1} t_* \sim \left\{ \eta \alpha^2 \left(\frac{m_p}{m_e}\right)^2 \right\} \alpha_G^{-1} \left(\frac{M}{M_\odot}\right)^{-2} t_p \quad (35)$$

The quantity in braces is of the order of unity; as stars must have a mass of the order of $M_\odot$ living observers could exist only when

$$t_0 > t_{\text{MS}} \sim \alpha_G^{-1} t_p \quad (36)$$

However, t_0 cannot be much bigger than t_{MS} or else most of the Universe would have been processed into white dwarfs, neutron stars or black holes. Therefore observers are most likely to exist at an epoch $t_0 \sim t_{\text{MS}}$, and they will find equation (32) automatically fulfilled.

In fact, t_0 exceeds the value of t_{MS} in equation (36) by a factor $m_p/m_e \sim 10^3$. However, t_{MS} is sensitive to the value of M and equation (36) is really appropriate only for an upper main-sequence star. Dicke's argument would therefore be more convincing if one could show that the first stars would be of low mass. A possible reason might come from the general argument^{11,12} that the mass scale at which a collapsing cloud must stop fragmenting is

$$M_{\text{frag}} \sim x^{-1/2} \left(\frac{kT}{m_p c^2}\right)^{1/4} M_\odot \sim 10^{-2} x^{-1/2} M_\odot \quad (37)$$

where T is the cloud's temperature (expected to be $\leq 10^4$ K) and x is the ratio of its luminosity to that of a black body with this temperature. M_{frag} has only a weak dependence on T and is at least an order of magnitude smaller than $M_\odot$, thus increasing t_{MS} to a value more comparable to t_0 . Alternatively, one might argue that the first stars do have $t_{\text{MS}} \ll t_0$ but that some of the elements vital for life must be generated through the s-processes associated with later-forming less massive stars.

The total mass associated with the observable Universe (the mass within the horizon volume) is $\sim \rho_0 c^2 t_0^3$ where ρ_0 is the

present matter density, given by the Friedmann equation:

$$\rho_0 = \frac{3H_0^2}{8\pi G} + \frac{Kc^2}{16\pi G} \quad (38)$$

Here K is the scalar curvature of the Universe. Providing the K term is smaller than the others, we deduce that the mass of the Universe is

$$M_u \sim c^3 t_0^3 G^{-1} H_0^2 \sim \frac{c^3 t_0}{G} \sim \alpha_G^{-2} \left(\frac{m_p}{m_e}\right) m_p \quad (39)$$

The fact that the number of protons in the Universe is of the order of α_G^{-2} , another cosmological coincidence, is thus explained providing one can justify neglecting the K term in equation (38). It has been argued that K must always be zero by appealing to Mach's principle¹³ but, apart from this, there may be anthropic reasons for expecting that the K term is small. If K is negative, galaxies could not have condensed out from the general expansion unless $(-K)$ were less than $G\rho/c^2$ at their formation epoch. Otherwise, their gravitational binding energy would not have been large enough to halt their expansion. $(-K)$ may, in fact, exceed $G\rho/c^2$ now, but not by a large factor. If K is positive, it must be $< G\rho_0/c^2$, otherwise the whole Universe would have recollapsed before $t = t_{\text{MS}}$. The simple relationship between M_u and t_0 given by equation (39), with equation (36), explains why the Universe must be as big and diffuse as it is to last long enough to give rise to life. Relationships (32) and (39) also mean that the Universe has an optical depth of the order of unity to electron scattering.

Galaxies: it is not certain how galaxies form, so any estimate of their scale is very model dependent. The scale indicated in Fig. 1 derives from the following argument¹⁴⁻¹⁶. We assume that galaxies originate from overdense regions in the gaseous primordial material, and that they have a mass M and radius R , when they become bound. After binding, protogalaxies may virialise at a radius $\sim R/2$. Thereafter, they will deflate on a cooling timescale, with a virial temperature

$$T \sim \frac{GMm_p}{kR} \quad (40)$$

Providing kT exceeds one Rydberg the dominant cooling mechanism is bremsstrahlung and the associated cooling timescale is

$$t_{\text{cool}} \sim \frac{1}{n\alpha\sigma_T c} \left(\frac{kT}{m_e c^2}\right)^{1/2} \sim \frac{m_e^2 c^3}{ae^4 n} \left(\frac{kT}{m_e c^2}\right)^{1/2} \quad (41)$$

The free-fall timescale is

$$t_f \sim \left(\frac{GM}{R^3}\right)^{-1/2} \quad (42)$$

and this exceeds t_{cool} when R falls below a mass-independent value

$$R_* \sim \alpha^4 \alpha_G^{-1} \left(\frac{m_p}{m_e}\right)^{1/2} a_0 \quad (43)$$

which, from a more precise calculation, is 75 kpc. Until a massive cloud gets within this radius it will contract quasistatically and cannot fragment into stars.

This argument applies only if the mass is so high that $kT_{\text{virial}} \gg \alpha^2 m_e c^2$ at the 'magic radius' R_* ; that is,

$$M \gg M_* = \alpha^{-2} \alpha^5 \left(\frac{m_p}{m_e}\right)^{1/2} = 10^{12} M_\odot \quad (44)$$

Gas clouds of mass $< M_*$ cool more efficiently owing to recombination, and can never be pressure supported. Thus, M_* is a characteristic maximum galactic mass. Primordial clouds of mass $> M_*$ are inhibited from fragmentation and may remain as

hot pressure-supported clouds. This type of argument can be elaborated and made more realistic¹⁴⁻¹⁶, but one still obtains a mass $\sim M_*$ above which any fluctuations are likely to remain amorphous and gaseous, and which may thus relate to the mass-scale of galaxies. M_* and R_* may thus characterise the mass and radius of a galaxy. Of all the scale estimates in Fig. 1, this is the least certain—the properties of galaxies may be a consequence of irregularities imprinted in the Universe by processes at early epochs.

This completes the justification of Fig. 1 except that we may eliminate the dependences on m_*/m_p using the relationship

$$m_*/m_p \sim 10\alpha^2 \quad (45)$$

which results from a coincidence in the nuclear physics (see equation (58)). From Fig. 1 some amusing interconnections can be deduced. Regarding the length scales, for example; $\text{man} \sim (\text{planet} \times \text{atom})^{1/2}$; $\text{planet} \sim (\text{Universe} \times \text{atom})^{1/2}$. Regarding the mass-scales: $\text{Planck} \sim (\text{exploding hole} \times \text{proton})^{1/2}$; $\text{exploding black hole} \sim (\text{Universe} \times \text{proton})^{1/2}$; $\text{man} \sim (\text{planet} \times \text{proton})^{1/2}$. These relationships cannot of course be regarded as coincidences as they can be expected *a priori*.

Other cosmological coincidences

Another dimensionless constant which characterises our Universe is the photon-to-baryon ratio $\mathcal{S} \sim 10^8 \Omega^{-1} \text{ g l}$ (where Ω is the baryon density in units of the critical density). According to the hot big bang model the background radiation dominated the density of the Universe until a time

$$t_{\text{eq}} \sim \mathcal{S}^2 \alpha_G^{-1/2} t_p \sim 10^{11} \Omega^{-2} \text{ s} \quad (46)$$

and thermally decoupled from the matter when T fell below $\sim 0.1\alpha^2 m_e c^2/k$ at a later time

$$t_{\text{dec}} \sim \mathcal{S}^{1/2} \alpha_G^{-1/2} \alpha^{-3} \left(\frac{m_p}{m_e}\right)^{3/2} t_p \sim 10 \text{ g l}^3 \Omega^{-1/2} \text{ s} \quad (47)$$

(These equations derive from the fact that the radiation density and temperature fall like R^{-4} and R^{-1} respectively. Here R is the length scale of the Universe, which is $\propto t^{1/2}$ for $t < t_{\text{eq}}$ and $\propto t^{2/3}$ for $t > t_{\text{eq}}$.) The observation that t_{eq} and t_{dec} are within an order of magnitude of each other (for $\Omega \sim 0.1$) corresponds to the coincidence

$$\mathcal{S} \sim 10\alpha^{-2} \left(\frac{m_p}{m_e}\right) \sim \alpha^{-4} \quad (48)$$

Now, the formation of galaxies cannot occur until, first, T has fallen below the decoupling temperature, and second, the radiation density has fallen below the matter density. Thus, the anthropic principle requires that t_0 exceeds both t_{eq} and t_{dec} these conditions being satisfied if

$$\mathcal{S} < \alpha_G^{-1/4} \left(\frac{m_p}{m_e}\right)^{1/2} \sim \alpha_G^{-1/4} \alpha^{-1} \sim 10^{11} \quad (49)$$

A lower limit on $\mathcal{S}$ is obtained if one requires that the Jeans mass in the period t_{eq} to t_{dec}

$$M_J \sim G^{-3/2} \rho^{3/2} \rho^{-2} c^3 \sim G^{-1} t_{\text{eq}} c^3 \sim \alpha_G^{-3/2} \mathcal{S}^2 m_p \quad (50)$$

exceed the galactic mass indicated by equation (44). Such a condition would have to be satisfied if one identified M_J with the mass of a supercluster of galaxies¹² and it implies

$$\mathcal{S} > \alpha_G^{-1/4} \alpha^{9/2} \left(\frac{m_p}{m_e}\right)^{5/4} \sim \alpha_G^{-1/4} \alpha^2 \sim 10^6 \quad (51)$$

Equations (49) and (51) constrain $\mathcal{S}$ to lie fairly close to its observed value.

The rough equality between t_{eq} and t_{dec} has prompted suggestions that the background radiation may have been generated in some way during the early history of the Universe. For example, the radiation may have been produced by a first generation of pregalactic objects¹⁷. Such objects have a characteristic

lifetime $\sim t_{\text{eq}}$ given by equation (35), so after t_{eq} the radiation density would be expected to be ηF times the matter density, where F is the fraction of the Universe which goes into the stars and η is the fraction of each star's rest mass released through nuclear energy generation and supernova outbursts. The value of t_{eq} associated with the generated $\mathcal{S}$ is thus $(\eta F)^{3/2} t_{\text{eq}}$ and equations (35) and (46) imply, for objects with $L \sim L_E$, that

$$\mathcal{S} \sim \alpha_G^{-1/4} \left\{ \alpha \left(\frac{m_p}{m_e}\right) F^{3/4} \eta^{5/4} \right\} \quad (52)$$

If the term in braces is of the order of unity, one would expect $\mathcal{S} \sim \alpha_G^{-1/4}$ as observed. The same relationship between $\mathcal{S}$ and α_G would apply if the radiation were generated by black holes accreting at the Eddington limit¹⁸. Another possibility^{19,20} is that a photon-baryon ratio of the order of

$$\mathcal{S} \sim \left(\frac{G m_W^2}{\hbar c}\right)^{1/4} \quad (53)$$

where m_W is the W-boson mass, could be generated by CP violating processes in primordial black hole evaporation, or by the large fluctuations which might arise at the epoch of weak/electromagnetic interaction symmetry breaking¹⁸. This is just the relation $\mathcal{S} \sim \alpha_G^{-1/4}$ with m_p replaced by m_W . One could probably conceive of several cosmological scenarios in which a value of $\mathcal{S}$ of the order of $(G m^2/\hbar c)^{-1/4}$ would be generated, where m is the mass of some elementary particle. The important point is that the coincidences involving $\mathcal{S}$ can be explained naturally without recourse to anthropic considerations. (The processes of primordial nucleosynthesis, apart from deuterium production, are insensitive to $\mathcal{S}$ provided that $\mathcal{S} \gg 10^3$.)

Dicke's anthropic interpretation² of equation (32) was advanced before the microwave background was discovered. One could perhaps replace (or strengthen) the argument leading to equation (36) by the more general statement—independent of considerations of stellar physics—that observers require $kT \ll 0.1\alpha^2 m_e c^2$ and the possibility of thermodynamic disequilibrium, and therefore could survey the Universe only when $t_0 \gg t_{\text{dec}}$. From equation (46), if $\mathcal{S} \sim \alpha_G^{-1/4}$ the condition $t_0 > t_{\text{eq}}$ is the same as equation (36).

Dicke's argument helps us to understand why the 'coincidence' of equation (32) prevails—why a similar large number arises in two contexts that might at first sight seem unrelated. It does not tell us why α_G^{-1} has its particular immense value. The task of deriving such a large pure number from basic theory might seem a daunting one. However, Zeldovich²¹ points out that a complete quantum theory of gravity, where tunnelling and topology changes play a key role, is likely to involve exponentials of pure numbers, so that a factor $\sim 10^{40}$ may readily arise. Although no such number has been predicted, a relationship between α and α_G may be forthcoming from quantum field theory. It has been suggested^{22,23} that all space integrals in quantum electrodynamics should be cut off at the Planck length (given by equation (7)), thereby reducing otherwise divergent integrals to finite functions of the parameter $(\alpha \log \alpha_G)$. Various arguments suggest that a self-consistent electrodynamics is possible only if this parameter has some specific value of the order of unity, that is, one requires

$$\alpha^{-1} \sim \log \alpha_G^{-1} \quad (54)$$

This argument may not be convincing, but empirically relation (54) is satisfied. Figure 1 mainly shows that all objects where gravity is important have masses exceeding m_p by some simple power of α_G^{-1} . As the scaling is so simple, could one envisage a hypothetical universe in which all microphysical laws were unchanged, but G was (say) a million times stronger? Planetary and stellar masses ($\propto \alpha_G^{3/2}$) would then be lowered by 10^9 ; but hydrogen-burning main-sequence stars would still exist albeit with lifetimes ($t_{\text{eq}} \propto \alpha_G^{-1}$ according to equation (35)) of only ~ 100 yr rather than $\sim 10^8$ yr. Moreover, Dicke's argument would still apply: a hypothetical observer looking at the

Universe when $t_0 \approx t_{\text{max}}$ would still find equation (32) fulfilled, although the number of particles in his universe would be 10^{12} times lower than in ours. Are there anthropic arguments against the 'cognisability' of the kind of small-scale speeded-up universe that corresponds to a much smaller α_G^{-1} ?

One might argue that the gradual evolutionary emergence of complex organisms demands a large ratio between cosmic and microphysical timescales, and requires also that organised structures can become large (masses $\gg m_p$) before gravity overwhelms chemical forces. This favours a very large α_G^{-1} ; moreover, as $M_*/M_\odot \propto \alpha_G^{-1}$, a universe where α_G^{-1} is large contains more independent sites where evolution might occur. But there is no basis here for being at all quantitative. There are, however, some more specific (though somewhat contrived) anthropic arguments that pin down α_G .

One connection between α and α_G , given by Carter^{3,24}, is related to the existence of convective stars. If radiation transport is unable to maintain a star's surface temperature T_s above the ionisation temperature $\sim 0.1\alpha^2 m_e c^2/k$, a convective outer layer develops and this supplements the heat transport so that it does. The value of T_s which can be maintained by radiative transport, assuming (from the Coulomb penetration condition) a central temperature $T_C \sim 10^{-2}\alpha^2 m_p a^2/k$, is

$$T_s \sim \left(\frac{L}{aR^2}\right)^{1/4} \sim (\text{optical depth through star})^{-1/4} T_C \quad (55)$$

T_s exceeds $0.1\alpha^2 m_e c^2/k$ provided M exceeds

$$M_* \sim M_\odot \alpha_G^{-1/2} \alpha^6 \left(\frac{m_e}{m_p}\right)^2 \sim M_\odot \alpha_G^{-1/2} \alpha^{10} \quad (56)$$

using relation (45). The mass M_* thus divides the (convective) red dwarfs from the (radiative) blue giants. This lies in the range, around $M_\odot$, in which main-sequence stars exist only because

$$\alpha_G \sim \alpha^{20} \quad (57)$$

Were G (and hence α_G) slightly larger, all stars would be blue giants; if it were slightly smaller, all stars would be red dwarfs. Carter ascribes anthropic significance to relation (57) on the basis that the formation of planetary systems may be associated with convective stars. (This is supported by the observation that red dwarfs have much less angular momentum than blue giants and a loss of angular momentum may be a consequence of planet formation, but this is not a compelling argument. Alternatively, convective stars may lose their angular momentum through a wind, and this wind, by blowing away the gaseous envelope of planets close to the star, facilitates the formation of solid planets with non-hydrogen atmospheres.) Carter infers that no planets, and hence no life, would form if α_G were much larger than α^{20} . If α_G were much smaller, all stars would be chemically homogeneous due to convective mixing and one would not get the 'onion-skin' shell structure which characterises pre-supernova models. Carter's convective condition^{12,14} is also the condition that the number of stars in a galaxy be the same as the number of galaxies in the Universe.

The constants pertaining to nuclear physics are the strong (scalar) coupling constant $f^2 \approx 15$ and the mass ratios $m_\pi/m_N \approx 1/1837$, $m_\rho/m_N \approx 1/7$ and $\Delta_N/m_N \approx 1/730$ where $\Delta_N = (m_N - m_p)$. (Many more mass ratios are associated with high-energy physics but it is not clear which of them are fundamental.) The important features of nuclear physics depend²⁴ on the following four coincidences:

$$\begin{aligned} f^2 &\approx 2m_N/m_\pi & \Delta_N/m_\pi &\approx 2 & \alpha &\approx \Delta_N/m_\pi & f &\approx 1/3\alpha^{1/2} \\ (a) & & (b) & & (c) & & (d) \end{aligned} \quad (58)$$

Equation (58a) implies that strong interactions are only marginally strong enough to bind nucleons into nuclei. If f were

slightly weaker, only hydrogen could exist; if it were slightly stronger nuclei of almost unlimited size might exist. (58b) implies that neutrons are unstable to β -decay in isolation but not in the presence of relativistic degenerate electrons. (58c) implies that the electrostatic energy in light nuclei $\sim \alpha m_e$ is comparable to the neutron-proton mass difference. (58d) implies that the electrostatic energy is small compared with nuclear binding energy in light nuclei but comparable to it for nuclei with $Z \sim (f\alpha)^{-3} \sim 30$, so such large nuclei are unstable to electromagnetic disruption. If the relations indicated by equation (58) were not satisfied, elements vital to life would not exist, so one might also ascribe anthropic significance to these relations. Note that the combination of (58a), (b), (c) and (d) implies equation (45). Kahn²⁷ noted that $m_e \ll m_p$ may be a prerequisite for complex chemistry, as this ensures that the ions are located to a precision $\sim (m_e/m_p)^{1/4}$ times their mean spacing.

There may be other anthropic aspects to the value of f . For example, elements heavier than helium can form in stars through the triple- α reaction ($\text{He}^4 + \text{He}^4 \rightarrow \text{Be}^8$, $\text{Be}^8 + \text{He}^4 \rightarrow \text{C}^{12}$), and it is apparently accidental that this process yields a substantial amount of carbon^{25,26}. ^8Be is unstable (otherwise the 'helium flash' in giants would lead to a catastrophic explosion); but the reaction proceeds to ^{12}C because this latter nucleus happens to have an energy level just above the sum of the energies of ^8Be and ^4He . There is, however, no similar favourably placed resonance in ^{16}O ; otherwise almost all the carbon would be transmuted into oxygen. If f were even merely a few per cent larger, there would be 100% cosmological helium production because He^2 would be bound, and deuterium could form by $p + p \rightarrow ^2\text{He} + \gamma$, $^2\text{He} \rightarrow \text{D} + e^+ + \nu$, even if there were no frozen-out neutrons. A small increase in f would also affect the binding energies of heavier nuclei.

Few features of the physical world seem to depend on the actual value of the weak interaction coupling constant. There are, however, two processes, both crucial to nucleosynthesis, which are sensitive to neutrino cross-sections and thus imply a coincidence of 'anthropic' relevance.

The first of these is connected with the production of helium through cosmological nucleosynthesis. The helium abundance Y is essentially determined by the temperature T_F at which the neutron-proton ratio freezes out. This occurs when the weak interactions ($p + e^- \rightarrow n + \nu$, $p + \bar{\nu} \rightarrow n + e^+$), proceeding at a rate $\propto g_w^2 T^5$, where $g_w \sim 10^{-49} \text{ erg cm}^3$ is the weak coupling constant, become slower than the cosmological expansion rate $\sim (GaT^4/c^2)^{1/2}$ at a temperature

$$kT_F \sim G^{1/6} g_w^{-2/3} \hbar^{11/6} c^{-5/6} \quad (59)$$

As virtually all the frozen-out neutrons burn into helium, the resultant helium abundance is

$$Y \sim \frac{2n_N/n_p}{n_N/n_p + 1} \quad \text{where} \quad \frac{n_N}{n_p} \sim \exp\left(\frac{-\Delta_N c^2}{kT_F}\right) \quad (60)$$

The fact that $Y \sim 25\%$ rather than 0% or 100% results only because $kT_F \sim \Delta_N c^2 \sim m_\pi c^2$ and, from equation (59), this derives from the 'coincidence'

$$\left(\frac{Gm_\pi^2}{\hbar c}\right)^{1/4} \sim \left(\frac{g_w m_\pi^2 c}{\hbar^3}\right) \quad (61)$$

The dimensionless number on the right may be regarded as the weak fine structure constant ($\alpha_w \sim 10^{-11}$) and the number on the left as the quarter power of the electron gravitational fine structure constant. In the Weinberg-Salam unified theory of weak and electromagnetic interactions²⁸ α_w is related to α by

$$\alpha_w \sim \alpha \left(\frac{m_e}{m_W}\right)^2 \quad (62)$$

So equation (61) combined with equation (45) may be written as

$$\alpha_G \sim \left(\frac{m_p}{m_W}\right)^8 \left(\frac{\alpha^2 m_p}{m_n}\right)^2 \sim \left(\frac{m_p}{m_W}\right)^8 \quad (63)$$

It is unclear to what extent these coincidences can be interpreted anthropically. Relation (63), for example, may reflect some deep-rooted connection between gravity and the weak and electromagnetic interactions. However, life could probably not exist if Y were 100% (as would be the case if α_W were slightly smaller), as there would be no water. Also, the lifetime of a helium star is less than that of a hydrogen star and might not be long enough to permit the evolution of life. It is not obvious that 0% helium production (as would arise if α_W were slightly larger) would be incompatible with life.

Equation (61) may, however, be associated with another anthropic condition (which would limit α_W in both directions)—the existence of supernovae. What actually ejects the stellar envelope in a supernova explosion is still uncertain, but it may be the outward surge of neutrinos generated by the high temperatures in the collapsing core³⁰. For this model to work, one requires the timescale on which neutrinos interact with nuclei in the envelope to be comparable to the dynamical timescale. If it were much longer, the envelope would be essentially transparent to the neutrinos; if it were shorter, the neutrinos would be trapped in the core, and could not escape to deposit their momentum in the less tightly bound surrounding layers. The two timescales are comparable if

$$c^{-3} \hbar^{-4} g_W^2 n (kT)^2 \sim (G n m_p)^{1/2} \quad (64)$$

where n is the nucleon number density. For the neutrinos to be produced at all (by $e^+ + e^- \rightarrow \nu + \bar{\nu}$) one requires kT to be of the order of $m_\nu c^2$. One also expects the density at the bounce to be of the order of the nucleon degeneracy density which, for $M \sim M_\odot$ is of the order of the nuclear density: $n \sim (\hbar/m_p c)^{-3}$. Putting these values for n and T into equation (64) gives relation (61) apart from a $(m_p/m_n)^{1/2}$ factor. Hence, the condition that stars go through a supernova phase is essentially the same as the condition that there be an interesting amount of cosmological helium production.

Conclusion

The possibility of life as we know it evolving in the Universe depends on the values of a few basic physical constants—and is in some respects remarkably sensitive to their numerical values. Indeed, the various anthropic relations quoted above in principle determine the order-of-magnitude of most of the fundamental constants of physics. Equations (54) and (57) specify α and α_G ; equations (61) and (58d) specify α_W and f ; and equations (9), (45), (58) and (63) determine m_p , m_n , m_e , and m_W in terms of the Planck mass. From a physical point of view, the anthropic 'explanation' of the various coincidences in nature is unsatisfactory, in three respects. First, it is entirely *post hoc*: it

has not yet been used to predict any feature of the Universe (although some people have used it to rule out various cosmological models). Second, the principle is based on what may be an unduly anthropocentric concept of an observer. The arguments invoked here assume that life requires elements heavier than hydrogen and helium, water, galaxies, and special types of stars and planets. It is conceivable that some form of intelligence could exist without all of these features—thermodynamic disequilibrium is perhaps the only prerequisite that we can demand with real conviction. Third, the anthropic principle does not explain the exact values of the various coupling constants and mass-ratios, only their order of magnitudes. With enough anthropic conditions, one may be able to be more precise about the constants of nature, but the present situation is unsatisfactory.

On the other hand, nature does exhibit remarkable coincidences and these do warrant some explanation. Apart from Dirac's suggestion¹ (which only considers the age of the Universe coincidence), the anthropic explanation is the only candidate and the discovery of every extra anthropic coincidence increases the *post hoc* evidence for it. The concept would be more palatable if it could be given a more physical foundation. Such a foundation may already exist in the Everett 'many worlds' interpretation of quantum mechanics, according to which, at each observation, the Universe branches into a number of parallel universes, each corresponding to a possible outcome of the observation³⁰. The Everett picture is entirely consistent with conventional quantum mechanics; it merely bestows on it a more philosophically satisfying interpretation. There may already be room for the anthropic principle in this picture. Wheeler³¹ envisages an infinite ensemble of universes, all with different coupling constants and so on. Most are 'still-born', in that the prevailing physical laws do not allow anything interesting to happen in them; only those which start off with the right constants can ever become 'aware of themselves'. One would have achieved something if one could show that any cognisable universe had to possess some features in common with our Universe. Such an ensemble of universes could exist in the same sort of space as the Everett picture invokes. Alternatively, an observer may be required to 'collapse' the wave function³². These arguments go a little way towards giving the anthropic principle the status of a physical theory but only a little: it may never aspire to being much more than a philosophical curiosity. One day, we may have a more physical explanation for some of the relationships discussed here that now seem genuine coincidences. For example, the coincidence $\alpha_G \sim (m_p/m_W)^8$, which is essential for nucleogenesis, may eventually be subsumed as a consequence of some presently unformulated unified physical theory. However, even if all apparently anthropic coincidences could be explained in this way, it would still be remarkable that the relationships dictated by physical theory happened also to be those propitious for life.

The possible role of superheavy elements in the early Moon is reviewed. The siderophilic superheavy elements (possibly $Z = 114, 115, 116$) may have been the heat source in the Moon's iron core needed to generate the ancient lunar magnetic field. It is suggested that in the search for present day evidence of the existence of these hypothetical elements, iron meteorites may be a key. The available data on their trace elements are reviewed and future work to determine whether they are in part fission products from metallic superheavy elements is suggested.

WE proposed recently¹ that superheavy elements (SHE) were present in the Moon at its accretional origin, 4.6×10^9 yr ago, in sufficient abundance to melt it in its entirety—thus forming a small iron core as well as the anorthositic highlands. Geochemists at first thought of a differentiation of the outer Moon only², which it was plausible to suppose might have been brought about by accretion³ or solar wind heating⁴, processes which are most effective in the outer layers. Lunar palaeomagnetism, interpreted as being acquired in a lunar field of internal origin at the time of the cooling of the lunar rocks, $3.2\text{--}4.0 \times 10^9$ yr ago, requires the existence of a molten iron core during this time⁵. Palaeointensity experiments show the surface lunar field to have been about 1 G 4.0×10^9 yr ago, a surprisingly high value, especially as the lunar core cannot be more than 500 km in radius. Fundamental thermodynamics of the convecting core dynamo show that a heat source of 10^{12} W is required in the iron core at that time to generate the inferred magnetic field⁶. It is shown that the various conventional heat sources, proposed over the last 30 yr for the geodynamo and shown to be quantitatively sufficient for its working, are not powerful enough for the early Moon.

Indeed we¹ suggested that those superheavy elements which were siderophilic ($Z = 107\text{--}111, 114, 115, 116$) might provide the necessary heat source for the ancient lunar core dynamo. Supposing that the SHE completely melted the Moon, they could account for the differentiation, which was completed by 4.4×10^9 yr, forming the two outer lunar shells of the outer anorthositic highland layer and the source region of the mare basalts, and they could have then been incorporated into the iron core.

In Fig. 1, dN/dt is the number of SHE fissions per year per kilogram of the Moon. It was shown that 3×10^8 nuclei per year per kg are required⁷ to fission at 4.6×10^9 yr ago to melt the

Moon, and 1.1×10^7 , 6.9×10^5 and 1.5×10^4 fissions per yr per kg are required to run the dynamo at 4.0×10^9 yr, 3.6 and 3.2×10^9 yr respectively. As these values of dN/dt lie on an exponential curve of 10^8 yr half life, SHE of this half life would explain the decay of heat sources in the early Moon.

Figure 1 also shows the rate of fission of SHE nuclei in the Moon's core, assumed to be 500 km in radius, expressed per kilogram of iron for the period 4.0×10^9 yr— 3.2×10^9 yr for which the palaeointensity of the field is known. Assuming the half life of 10^8 yr previously obtained from these data, another ordinate scale can be drawn giving the abundances of SHE in the iron at various times. If the palaeointensity of the younger rocks is underestimated, as has been suggested, then it is possible to produce a plot in which the present day abundance of SHE is of the order of that claimed by Flerov⁸ in carbonaceous chondritic meteorites. The half life given by this procedure is 1.6×10^8 yr and an ordinate scale giving abundances can be drawn corresponding to this value. Also it was shown that this empirical relation gave as the original abundance of SHE in the Moon about 0.1 that of cosmic abundance of uranium.

Fig. 1 Rate of fission of superheavy elements versus age in the early Moon (ordinate scale, left-hand side). Abundance by weight of the superheavy elements versus age in the Moon (ordinate scale, right-hand side).

Trace elements in iron meteorites

We have reviewed¹ the many efforts that have been made to search for evidence of SHE in nature. In this article we direct attention to the iron meteorites. We think that it is remarkable that bodies of all sizes in the Solar System (parent bodies of meteorites, the asteroid Vesta, the terrestrial planets, and the Moon) show evidence of early melting and it is a plausible hypothesis that the cause was the same. When early melting of orbiting bodies in the Solar System occurred, siderophilic elements would have accumulated in the iron phase. Half lives of 10^6 yr leave little chance of detecting SHE in iron meteorites today, but the fission products should still remain in the iron.

Figure 2 shows measurements⁹ made in iron meteorites of concentrations of elements heavier than iron. Peaks at $Z \sim 43$, $Z \sim 52$ and $Z \sim 78$ with maximum concentrations of about 10 p.p.m. (kg of element/kg of iron) are clearly present: we consider these peaks to be significant, despite the paucity of measurements and the difficulties in the mechanical separation of inclusions, such as sulphides and silicates, from the iron phase. Figure 3 shows that there is evidence for two of the peaks in the more primitive carbonaceous chondrites; they also occur (with much smaller amplitude relative to iron) in the Cameron¹⁰ curve of abundance of elements in the primitive solar nebula around $Z = 53$ and 78 (magic numbers) where the peaks have an abundance roughly 10^{-6} relative to iron. We must therefore conclude that the iron meteorites have not taken up, either in the process of condensation from the solar nebula or from any late processes of differentiation and melting in the 'parent body', any appreciable amounts of the other elements. This has been explained following Goldsmidt¹¹ by classifying the former elements as siderophile and the latter as lithophile; we attempt here a quantitative treatment. To establish whether the shapes of these peaks are entirely explained by the solubilities in iron of the elements originally present in the solar nebula we have made

Fig. 2 Abundance of elements measured in iron meteorites versus Z (see ref. 9). Dashed line shows suggested fission product distribution.

the following computation. We assume that the liquid metals obey the perfect solution law, that is, the solubility S_s is equal to the reciprocal of the ratio of the vapour pressure of the pure solute to the ambient pressure over the solution. Based on this assumption we have computed the expected concentration of the metallic elements in iron at the freezing point of iron.

We further assume that if an element's oxide is stable at $1,535^\circ\text{C}$, the melting point of iron, it will not be miscible with iron and so its concentration in iron meteorites will be zero. This assumption produces zeros in the theoretical curve of concentration against Z , from $Z = 33$ to $Z = 39$ inclusive and from $Z = 52$ to 71 inclusive. For the light elements this assumption is also true, and, in particular aluminium oxide is very stable and will never be found in iron: thus ^{26}Al on our theory is not plausible as a heat source in an iron core as has been suggested¹². (In any case its short half life of 0.73×10^6 yr rules it out as a heat source for the Moon's dynamo.) Similarly, halogens form hydrogen halides in a hydrogen-rich solar nebula and are immiscible in iron therefore. We have further assumed that the rare gases are insoluble in iron.

For those elements which are not rare gases, not halogens, and which do not have very stable oxides, their heats of vaporisation ΔH are computed using Trouton's rule: $\Delta H = (25) \times (\text{boiling point, K}) \text{ cal mol}^{-1}$. Putting this value of ΔH into the Clausius-Clapeyron equation, P_s , the vapour pressure of the given element as pure liquid at the freezing point temperature of iron (chosen as the lowest temperature at which a solute element could dissolve in iron) is calculated. Similarly the vapour pressure P_{Fe} of iron at its melting point temperature is computed. Assume a solar nebula at 1 atm pressure, containing 10^{12} atoms H, $10^{6.9}$ atoms Fe (designated as $n_{\text{Fe-O}}$), and numbers of atoms of each element (designated as $n_{\text{S-O}}$) equal to its cosmic abundance relative to hydrogen at 10^{12} . Let the number of solute atoms in the vapour at the melting point of iron be $n_s = P_s V kT$ and the number of iron atoms in the vapour similarly be $n_{\text{Fe}} = P_{\text{Fe}} V kT$. If S_s is the mole fraction of solute in the condensed system at the freezing point of iron, $S_s = P_s / P_{\text{S-O}}$. Then, using conservation of numbers of atoms,

$$n_{\text{S-O}} = m_s + (n_{\text{Fe-O}} - n_{\text{Fe}}) \times S_s / (1 - S_s)$$

which, with some rearrangement, yields the relation (using $V/kT = 10^{12}$ and using $S_s \ll 1$),

$$S_s = n_{\text{S-O}} (10^{12} + (n_{\text{Fe-O}} - n_{\text{Fe}}) / P_{\text{S-O}})^{-1} \times (P_{\text{S-O}})^{-1}$$

where $(N_{\text{Fe-O}}) = (n_{\text{Fe-O}})$ is the number of condensed iron atoms.

Simple reasoning by analogy leads one to guess that the SHE elements of lower Z (114, 115, 116) would be siderophilic, whereas elements of $Z = 121$ to 138 probably would have a chemistry like that of actinium and lanthanum, and that they would form stable oxides in a water-rich nebula and could not have existed in iron meteorites. However, elements of $Z = 121$ –138 are g -orbital elements of which we have no chemical experience. So it is possible that our capability of predicting their solubility in iron fails in this range of Z . Elements 107–111 almost certainly will be iron soluble.

Table 1 lists the theoretical solubilities in iron versus Z , calculated by the method discussed above and the measured concentrations versus Z . In general the calculated solubilities in iron fit the observations in iron meteorites for about half the metallic elements, which have long been recognised as siderophiles, but they are lower than the observed ones in most other cases. The differences in concentrations—those found experimentally minus those calculated—provide evidence of strong peaks around $Z = 32$, $Z = 46$, $Z = 50$ and $Z = 77$. These differences, plotted in Fig. 4, agree well with the peaks in the experimental measurements of heavy elements in iron meteorites. Furthermore, the highest values of peak elements occur in those metal meteorites with the largest crystals having cooled the most slowly. In addition, we have evidence for the presence of Zn, the halogens, the noble gases, the rare earths, and the actinides, none of which should be present in an iron phase according to our theory. Experimental confirmation of the

* Excess is the difference between the measured and calculated concentrations in p.p.m. by weight.

theoretical calculations is lacking and is much needed.

From the point of view of physical chemistry, these results are only a first approximation. The basic consideration is whether the assumption of equilibrium with the nebular gases at the time of freezing of the iron rich phase is valid. Many workers on iron meteorites assume that further fractionation via formation of 'parent bodies' and subsequent break-up to form the meteorites occurs. We suggest that this may not be so and that the slow cooling required by the Widmanstätten etch patterns may have been due to the presence of superheavy elements furnishing heat by radioactive decay, thus locking the cooling rate into their radioactive lifetimes.

Fission of superheavy elements

The sum of the nuclear charges of the two middle mass peaks equals $Z = 94-96$; but because the oxides of uranium and plutonium are very stable, these elements cannot be present in iron meteorites in quantities sufficient to explain these two peaks as the products of their fission: nor does the measured concentration of uranium in iron meteorites permit this explanation as will be discussed below.

The sum of the nuclear charges for the peaks at $Z \sim 46$ and $Z \sim 78$ is 121, and the sum for those at $Z = 52$ and $Z = 78$ is 130. Thus, if two superheavy elements had produced these peaks by fission, their nuclear charges would have ranged from 110 to 120. The width of the peak at $Z \sim 78$ is equal to twice the width of the peak at $Z \sim 43$. For this reason we have drawn the second peak, at $Z \sim 52$, in such a way that it has the same width as the peak at $Z \sim 43$, to account for the enhanced width at $Z \sim 78$, suggesting that indeed two superheavy elements are the progenitors. However, some theorists^{13,14} prefer superheavy elements in the low Z end of the island of stability, $Z = 114$, 115, 116, to be the most stable and these, as we have seen, are the only ones, on present chemical reasoning, to be siderophile.

The sum of the charges of three peaks in Fig. 2 corresponds to $Z = 168-180$. Since nuclear shell theory predicts a further island of stability at $Z = 164-184$ (depending on which potential energy function is favoured)¹⁵, we must consider whether the three peaks originate from decay of super-superheavy elements

(SSHE) by ternary fission. Although uranium and plutonium decay by ternary fission with only very low probability, it is possible that the geometry of the super-superheavy elements is such that ternary fission becomes the most probable mode of decay. The shape of the nucleus in its ground state could then be deduced from the shapes of the peaks of the fission product distribution. The shape might, for example, be bent and lumpy, perhaps like a water molecule, or perhaps like a three-legged starfish. According to recent theoretical ideas¹⁶, such nuclei

Fig. 3 Excess abundance of elements in iron meteorites above that expected on solubility theory.

($Z \sim 173$, $N \sim 249$) could have three axes of rotational symmetry.

Our hypothesis that the peaks result from the decay of SHE and SSHE in the early Solar System encounters some quantitative difficulties. If energies released on fission by the SHE and SSHE are ~ 250 MeV, then the peaks of concentration at about 10^{-5} g g $^{-1}$ would imply that in the early cores of the parent bodies a total energy release of about 2×10^4 J kg $^{-1}$, sufficient to vaporise iron. However, radiative cooling would prevent this. At the melting point of iron, 1,535 °C, and with a mean life of Y yr for spontaneous fission, an iron sphere taken as a black body would radiate at the fission rate for any values of Y longer than 1 Myr for spheres of radii less than 3,000 km. However, from the studies of the Widmanstätten patterns and kamacite bands¹⁷, we know that the cooling rates of iron meteorites must have been of the order of 1 °C Myr $^{-1}$. This probably requires the parent bodies of the iron meteorites to have been a loosely held aggregate in order to allow radiative cooling. Such a model for them may be required to explain why they were broken up by external forces, possibly tidal. We conclude that for iron meteorites early solidification is probable, with sealing-in of a substantial part of the fission products. Scott and Wasson¹⁷ discuss the classes of iron meteorites: only some may have originated as cores of small planetary bodies. The data we have used include all iron meteorites together; plots like that of Fig. 2 should be made for each class when sufficient measurements are available.

Another difficulty for the hypothesis is that the peak concentrations of the hypothetical fission products are about 10^{-5} kg kg $^{-1}$ and would imply, assuming a maximum fission yield for an element of 5%, that the initial abundance of SHE in the early Solar System, allowing that they became concentrated in iron by a factor of 10–100 would have been between 2×10^{-6} and 2×10^{-5} kg kg $^{-1}$. This is to be compared with a cosmic abundance of 10^{-7} for uranium. Recent calculations of the r process suggest a cosmic abundance of SHE within an order of magnitude that of uranium¹⁸. If this were so, and if the SHE most likely to have been present were those with $Z = 114$ for the two reasons already given, then the fission peaks expected by analogy with uranium should be near $Z = 50$ and $Z = 80$ and with abundance 5×10^{-8} – 5×10^{-7} . If the peaks which we have

Fig. 4 Abundance of elements in carbonaceous chondrites. Dashed line shows suggested fission product distribution.

discussed are after all the result of elements being taken up from the solar nebula by fractionation processes and as a result of extraction of elements into the iron phase during iron-silicate fractionation, then, as there is a window around $Z = 55$ – 70 where the expected fission peaks should lie, better data on rare earth abundances should enable their presence to be determined. So far virtually no data are available.

In iron meteorites the abundance of uranium is 10^{-10} – 10^{-12} (see ref. 19), completely inadequate to explain the 10 p.p.m. of lead and the several parts per million of Sn, Sb, Te and I found in iron meteorites and cannot explain the Xe and Kr which has recently been detected^{20,21} in iron meteorites with concentrations of about 10^{-12} because their isotopic ratios are not those of fission products.

In the so-far unsuccessful attempts to make SHE in accelerators, collisions of heavy ions have been used²². We note that in collisions of ^{40}Ar (~ 300 MeV) and ^{84}Kr (~ 600 MeV) with ^{238}U , three peaks of heavy element concentrations were produced²² at about the same values of Z as those of the peaks for the iron meteorites (Fig. 2). It is as if perhaps SHE of $Z = 110$ – 120 were being produced but their neutron/proton ratio was too small and their excitations too large to allow them to live long after the collision.

If indeed the peaks are made by fission products of SHE in iron meteorites, the wide separations of the peaks indicates a very asymmetric mode of binary fission. Asymmetric fission was predicted by Rao²³ at the very values of Z and N which characterise the peaks in Fig. 2. They centre around the 'magic numbers': for the peak at $Z = 46$, the magic number is $N^* = 50$; the peak at $Z = 50$ centres around the two magic numbers, $N^* = 82$ and $Z^* = 50$; and the peak at $Z = 78$ centres around the two magic numbers $N^* = 126$ and $Z^* = 82$. We believe that decay of superheavy elements initially present in supernova remnants is partly responsible for the peaks mentioned above in the carbonaceous chondrite abundances. It would be strange if the abundance peaks observed in the iron meteorites were to be entirely explained by their siderophile character. Why would elements with magic numbers in their nuclear structure also have the chemical property of solubility in iron?

Classical theory of iron meteorites

E. R. D. Scott²⁵ states that "all major groups (of iron meteorites) were produced by fractional crystallisation of an iron melt. Meteorites did not form a single molten core. The cooling rates estimated from kamacite bandwidths and bulk nickel contents do not support a core origin from some groups. The wide range of cooling rates suggested formation of these meteorites in isolated regions of a parent body. Metre-sized molten iron pools formed. Unless it can be shown that other factors (such as the effect of trace and minor elements on diffusion rates) are responsible for the wide range of cooling rates estimated, such data are not compatible with core formation. The primary fractionation which established the chemical differences between the groups might have occurred during condensation of the solar nebula. It seems unlikely that the major differences could have been produced during separation of metal, silicate, and sulphide phases in parent bodies."

J. T. Wasson²⁶ suggests that "All currently available evidence favours the viewpoint that meteorites formed at relatively low ambient pressures, much less than those found in the interior of a moon-sized body, and consistent with an origin in parent bodies no larger than the largest asteroids. Now that a low-pressure origin of the meteorites is widely accepted, ... some, perhaps many, probably originated in the smaller asteroids, with central pressures less than 100 bar ... the minimum size of the parent body can be estimated, the total mass is 0.8×10^{15} g, 650 Myr ago. At a density of 7.9 g cm $^{-3}$, the minimum radius is 0.3 km. This lower limit is much smaller than parent body sizes necessary to account for estimated cooling rates." Thus while we acknowledge that many people have worked intensively to understand the mysterious properties of iron meteorites for at

least 40 yr, many of the properties of iron meteorites are inexplicable by the classical ideas of their origin. We hypothesise that the iron meteorites were never very large, condensed from a solar nebula in small masses containing superheavy elements soluble in iron-nickel melts, cooled very slowly because of a radio-half life of about 100 Myr, and produced solid iron-nickel chunks supersaturated in fission products which ranged from $Z = 30$ to 92, and perhaps an even wider distribution of elements of charge Z .

Conclusions

Our hypothesis that the heavy elements in iron meteorites are partly the fission products of SHE and perhaps of SSHE is put forward tentatively as befits our state of ignorance in this field. But we suggest some definitive measurements to test it: (1) measurements of heavy element concentrations in each class of iron meteorites and of halides, alkalis, alkaline earths, and rare gases in particular; (2) measurement of solubilities of heavy elements in iron versus pressure and at high temperatures, to test our crude calculations; (3) study of the theory of ternary fission in SSH elements; (4) bombardment of uranium with uranium ions²³ in the heavy ion accelerators to determine if the heavy element peak at $Z \sim 78$ increases in height relative to that observed in Ar-U and Kr-U bombardments²⁴, and bombardment of U with Xe ions, for the same purpose; and (5) further work on isotope ratio analyses of peak elements.

We thank R. Hutchison, J. Kerridge, E. R. D. Scott and J. Wasson for discussions.

Transfer of actinides from the English Channel into the southern North Sea

C. N. Murray*, H. Kautsky & H. F. Eicke

Deutsches Hydrographisches Institut, 2000 Hamburg 4, FRG

Results are presented for ^{238}Pu , $^{239+240}\text{Pu}$, ^{241}Pu , ^{241}Am , ^{242}Cm and ^{244}Cm in waters of the English Channel and southern North Sea. Based on actinide concentration ratios in these waters compared with expected fallout values, the activities measured are considered to be mainly due to releases of low-level waste from the La Hague fuel reprocessing plant. Measurements made on ^{242}Cm indicate that any support by ^{242m}Am would be minimal.

As part of a study of the distribution, behaviour and sources of actinide isotopes in the North Sea, two series of surface water samples were taken during February-March and September-October 1975, concentrating especially on an area of the southern North Sea and the English Channel. This area is of particular interest because of the situation of a nuclear fuel reprocessing plant at La Hague near Cherbourg, as well as various nuclear power installations on coastal or estuarine sites in countries bordering this region. Previous work¹⁻³ has shown that important amounts of various fission radionuclides originating from releases of low-level wastes find their way into waters of the North Sea.

Murray and Kautsky⁴ have shown that waters entering the northern North Sea by the Pentland Firth and to the north of the Orkney Islands also transport detectable quantities of $^{239+240}\text{Pu}$ and ^{238}Pu resulting from discharge from fuel reprocessing plants at Windscale and to a much lesser extent, Dounreay. We report here the results of measurements of isotopes of three actinide elements, plutonium, americium and curium, in waters of the English Channel, whose activities are also believed to result

from waste discharge. These waters act as input source of several isotopes into the southern North Sea. Comparisons of various actinide activity concentration ratios for these waters with those that may be expected from fallout have been used to identify the source and the extent of their penetration.

Sampling and analysis

Samples of surface seawater, varying in volume between 60 and 200 l, were taken at 13 stations in the Channel and North Sea between 50° and 55° N during February-March, and September-October 1975. The samples were immediately acidified on collection and stored unfiltered in plastic drums until their subsequent analysis. Separation and measurement of the samples were carried out within three months of collection. The chemical separation and measurement by α spectrometry of the various actinide isotopes and the measurement of IAEA intercalibration samples have been described elsewhere⁵. After initial measurements of $^{239+240}\text{Pu}$, ^{238}Pu and ^{241}Am , the disks containing plutonium were stored for nearly two years so that ^{241}Pu (β emitter) could be measured from the ingrowth of its daughter isotope ^{241}Am (for a detailed discussion of this procedure see ref. 6). Due to the short time between sample collection and analysis, initially separated ^{241}Am is assumed to contain a negligible contribution of ^{241}Am due to ^{241}Pu decay between collection and analysis. Where activity levels were sufficiently high, measurements were also made of ^{242}Cm and ^{244}Cm . The decay of ^{242}Cm was traced on a single sample for nearly three years to determine whether some fraction of it was supported by ^{242m}Am .

Ratio of actinides in fallout

Hardy *et al.*⁷ have discussed the global inventory and distribution of fallout plutonium caused by atmospheric nuclear-weapon testing; from their data an average $^{238}\text{Pu}/^{239+240}\text{Pu}$ ratio

* Present address: Commission of the European Communities, JRC Ispra Establishment, Chemistry Division, 21020 Ispra (Varese), Italy.

‡Corrected for decay to date of collection.

of 0.04 can be calculated for integrated soil samples for 1970–71. They estimate that the accidental release of ^{238}Pu from the SNAP 9A satellite almost tripled the global deposition of this isotope by 1970.

Livingston *et al.*⁶ have reported that the $^{241}\text{Pu}/^{239+240}\text{Pu}$ ratios for fallout-contaminated marine samples are similar to those from fallout-contaminated soils. They showed, however, that these ratios are clearly different in samples from planned or accidental plutonium releases. Whereas the global fallout activity $^{241}\text{Pu}/^{239+240}\text{Pu}$ ratio on 1 January 1970 was calculated to be 8.2, the ratio in IAEA intercalibration samples, which are known to originate from areas contaminated by waste effluent from a major fuel reprocessing plant, was found to be about 30.

Fukai *et al.*⁸ measured the activity ratio of $^{241}\text{Am}/^{239+240}\text{Pu}$ in Mediterranean surface waters sampled in 1975 as 0.055 ± 0.007 . Results¹⁰ for North Atlantic surface water gave a range of ratios of 0.05–0.28, which agree with the estimate of Krey *et al.*¹¹ for 1974 for integrated global fallout of 0.22. Livingston *et al.*⁶ calculated the increase of the $^{241}\text{Am}/^{239+240}\text{Pu}$ ratio due the decay of fallout ^{241}Pu with time and for 1975 a value of about 0.18 was determined.

Holm and Persson⁹ and Bowen and Livingston¹² have discussed the occurrence of ^{242}Cm and ^{244}Cm in the environment. The former report that the average $^{242}\text{Cm}/^{239+240}\text{Pu}$ ratio in lichen for the period 1961–72 was $(0.3 \pm 0.1) \times 10^{-4}$. They also estimated the $^{244}\text{Cm}/^{239+240}\text{Pu}$ activity ratio to be about 0.2×10^{-4} , which agrees well with the observations of Bowen and Livingston¹². Both groups of workers assumed that ^{242}Cm was supported by ^{242m}Am , due to the age of the samples and the relatively short half life of ^{242}Cm (163 d).

On the basis of these expected fallout ratios an attempt has been made to distinguish the probable source and dispersion of actinides entering the southern North Sea from the English Channel.

Results and discussion

Figure 1 shows the positions of the sampling stations measured during February–March, and September–October 1975. Results for surface water activities of ^{238}Pu , $^{239+240}\text{Pu}$, ^{241}Pu , ^{241}Am , ^{242}Cm and ^{244}Cm are presented for both cruises in Table 1; all activities are corrected to the date of sampling. The concentrations for ^{238}Pu , $^{239+240}\text{Pu}$ and ^{241}Am for the February–March cruise have been presented elsewhere⁴ but these results are needed for calculation of isotopic ratios and are, therefore, included.

Kautsky¹³ has shown that patches of water of greatly varying ^{137}Cs activity enter the southern North Sea from the English

Channel at irregular intervals, rather than as a steady input. He proposed that this probably reflected irregular discharge by the La Hague fuel reprocessing plant. Such irregular discharges probably characterise the input of actinides as well.

As there are no available data for the variations in amounts of radionuclides discharged by the French plant as a function of time, a difficulty arises in trying to separate differential actinide behaviour due to chemical reactivity (towards biological or sedimentological processes) from discharge compositional fluctuations and contributions from fallout.

An indication of the pulse-like nature of the actinide discharge in the English Channel may be obtained by comparing

Fig. 1 Sampling stations February–March, and September–October 1975 cruises.

Table 2 Variations in channel water activity ratios occurring between February–March, and September–October 1975 cruises

concentrations at stations 52–56 (February–March 1975) and 30–34 (September–October 1975): these results are shown in Table 2. Although dilution occurs during the movement of water through the Channel, the variation in activity for ^{238}Pu , $^{239+240}\text{Pu}$ and ^{241}Pu , calculated as isotope activity in March divided by isotope activity in October (assuming that the dilution will be similar for both cruises), shows a remarkably similar pattern; the activity decrease for the isotopes being 2.8, 3.4 and 2.5 respectively. Thus the plutonium isotopes' water activity in the English Channel for March 1975 seems to have been some three times greater than that occurring for October 1975.

In the case of ^{241}Am a change in activity of about 2 occurs in the region of Cap de La Hague during the same period. The activity ratio in the Straits of Dover (stations 56/34, March–October), however, is about 0.9. As the ingrowth of ^{241}Am from ^{241}Pu will affect both concentrations equally, the difference may be considered real.

The results for ^{242}Cm are more complicated because of its relatively short half life of 163 d. Kautsky¹³ estimated the average speed taken for water to pass from Cherbourg to the Straits of Dover as about 1.7 nautical miles per day. The time it would take from Cherbourg to the Straits of Dover, a distance of ~160 nautical miles, would thus take some 100 d or somewhat less than one half life of ^{242}Cm . Assuming that both dilution and decay will affect the samples from the two cruises equally, it can be seen that ^{242}Cm activity in the English Channel in March 1975 was some 5.5 times greater than in October 1975.

It thus seems that the average concentration fluctuations for plutonium isotopes in the English Channel during March–October 1975, were reasonably constant. However, when one compares the fluctuations between the elements, large variations can be seen to occur; with decrease in the order $\text{Cm} > \text{Pu} > \text{Am}$. That the activities measured in the English Channel are not primarily due to fallout but may be attributed to the discharge of low-level waste from La Hague is shown by comparing the various isotope activity ratios in Table 3 with those that can be expected from fallout. In the case of plutonium isotopes the fallout $^{238}\text{Pu}/^{239+240}\text{Pu}$ ratio for integrated samples is about

0.04 ± 0.01 (2σ error) based on the results of Hardy *et al.*⁷. The ratios found in the channel region are about 0.20 for both cases. Even in the southern North Sea as far east as about $53^\circ 00' \text{N}$, $04^\circ 00' \text{E}$, plutonium activities are clearly due to sources other than fallout.

The results for the activities of ^{241}Pu found during both periods in 1975 are considerably higher than those of $^{239+240}\text{Pu}$. The values near Cap de La Hague are 30–50 times greater and are significantly different from those expected from fallout. The ^{241}Pu activity for station 56, February–March 1975 is 3–4 times lower than for other stations in the region. The reason for this anomalously low result is not clear, however, the $^{241}\text{Pu}/^{239+240}\text{Pu}$ ratios are generally comparable with those reported for 1972–74 by Hetherington *et al.*¹⁴ who also reported a large variability in the Windscale effluent ratio of 38.

The absolute activities of ^{241}Am in Channel water for both cruises are 5–10 times greater than those for Mediterranean surface water contaminated only by fallout. Average activities of about 0.06 fCi l^{-1} have been reported by Fukai *et al.*⁸ and Livingston *et al.*¹⁵. East of the Straits of Dover it becomes difficult to characterise the source of americium in surface seawater although it is clear from the $^{238}\text{Pu}/^{239+240}\text{Pu}$ ratio that plutonium entering the southern North Sea can be seen at least as far as $52^\circ 00' \text{N}$. The significantly higher ^{241}Am activities at stations in the Channel can, however, be attributed to discharges by the French plant.

An indication of a difference in behaviour of americium and plutonium may be deduced if one considers the $^{241}\text{Am}/^{239+240}\text{Pu}$ ratio. If on the basis of Kautsky's¹³ estimated transport velocity of about 1 nm d^{-1} for water moving from Cherbourg to the German Bight, a period of about 0.7 yr is required for activity to reach $52^\circ 00' \text{N}$. The ingrowth of ^{241}Am from ^{241}Pu for a $^{241}\text{Pu}/^{239+240}\text{Pu}$ isotope ratio of 40 would produce, in this time, an *in situ* increase in the measured $^{241}\text{Am}/^{239+240}\text{Pu}$ ratio of about 0.04, supplementing that due to direct input of ^{241}Am from La Hague. Taking expected fallout $^{241}\text{Am}/^{239+240}\text{Pu}$ ratios in surface waters to range between 0.05 and 0.28, no significant differences from fallout for either the Channel or the southern North Sea can be detected for the two cruises. However, the absolute ^{241}Am activities are clearly significantly different from fallout in the Channel, compared with those in the southern North Sea where plutonium activities due to waste discharge are to be seen. Thus the rate of disappearance of americium introduced from fuel reprocessing plants into surface waters is apparently considerably faster than for plutonium. This behaviour has also been reported¹⁶ for americium discharged into the Irish Sea. In the case of fallout for Mediterranean water Livingston *et al.*¹⁵ have also shown that a more rapid loss of ^{241}Am occurs.

Only a small number of samples from the English Channel showed detectable levels of ^{242}Cm and ^{244}Cm . On the basis of a comparison of ratios of $^{242}\text{Cm}/^{239+240}\text{Pu}$ and $^{244}\text{Cm}/^{239+240}\text{Pu}$

^{242}Cm , half life = 163 d; ^{241}Am , half-life = 433 yr; $^{242\text{m}}\text{Am}$ = 152 yr. Error, 1 σ propagated.

from fallout of around 0.3×10^{-4} and 0.2×10^{-4} respectively, it is clear that these samples contain curium originating from the French fuel reprocessing plant: ratios of greater than 0.1 and 0.01 respectively were determined. Although ^{244}Cm was not detected during February–March 1975, small amounts were measured during September–October 1975. In the case of ^{242}Cm the decrease in activity was much larger than for the other actinide isotopes; the September–October activities in the Channel being about 20% of those for February–March.

The non-detection of ^{244}Cm during February–March 1975 is remarkable, especially in view of the fairly high ^{242}Cm activities in the Channel, and seems to confirm the variability, both compositionally and quantitatively, of the discharges from the French fuel reprocessing plant.

It is difficult to estimate the degree of actinide penetration eastwards into the southern North Sea. From $^{238}\text{Pu}/^{239+240}\text{Pu}$ ratios it seems that the region about 53° 00' N, 04° 00' E is the furthest point where the source of plutonium is known to be due to waste discharge. The somewhat increased ratios of $^{241}\text{Pu}/^{239+240}\text{Pu}$ in this area compared with those reported for fallout⁶ might indicate the appearance of actinide activity from nuclear fuel reprocessing operations moving slowly eastwards.

Murray and Eicke¹⁷ have shown that although actinide activity levels along the German North Sea Coast in 1975 were mainly due to fallout, over 75% of the measured ^{137}Cs could be attributed to fuel reprocessing plants in both the UK and France. As they point out, base-line values obtained for the German North Sea and Baltic coastal waters may be valuable in showing possible changes in concentrations of actinides in these areas that might occur in the future, as well as helping to identify the source.

An attempt has been made to determine whether ^{242}Cm was supported by $^{242\text{m}}\text{Am}$. The decay activity of ^{242}Cm was measured in sample 52 taken on the February–March 1975 cruise, at intervals over a period of about 3 yr. The results are shown in Table 4. Using the procedure outlined by Dutton and Lovett¹⁸, a regression line calculated by the method of least squares gave a half life of 179 ± 25 d. This compares to a 163-d value for the

pure isotope. The fact that the 1 σ error in the half life includes the standard half life of ^{242}Cm precludes the possibility of determining the existence of $^{242\text{m}}\text{Am}$. However, the establishment of its existence using the method described by Dutton and Lovett¹⁸ would require samples containing very much higher activities (to obtain small measurement errors) than those of the seawater measured in the present case. The possibility remains, nevertheless, that measurement of these samples after a period of more than 10 half lives of ^{242}Cm might reveal some residual activity.

Conclusions

The variations of activity concentrations in the English Channel between March and October 1975 have demonstrated the pulse-like nature of actinide contamination entering the southern North Sea. Comparing actinide ratios in these waters with those expected from fallout, it has been shown that the major input of the isotopes is the French nuclear fuel reprocessing plant at La Hague.

Although plutonium water activities probably only represent a small percentage (<5%) of the total released in low-level wastes, this fraction shows a surprisingly high degree of mobility. Considering the various differences in behaviour of these elements it is clearly necessary to develop methods for the analysis of their chemical forms.

Finally, as the European nuclear generating and reprocessing capacity increases over the next few decades, the level of discharge could also increase. Actinide activities in the North Sea, although at very low concentrations, may reflect this evolution in nuclear technology.

We thank Dr M. Hoppenheit for his contribution and Miss M. Domian for technical assistance.

Nerve fibre topography in the retinal projection to the tectum

J. H. Scholes

MRC Cell Biophysics Unit, University of London, King's College Biophysics Department, 26–29 Drury Lane, London WC2, UK

The orderly layout of visual fibres in the optic nerves of cichlid fishes suggests that they are guided most of the way to the brain by contact with their neighbours. Before they reach the visual map in the tectum, however, their arrangement in the cross-section of the nerve is reorganised in a way which requires longer-range guidance.

RETINAL nerve fibres in vertebrate animals grow out of the eye during development, cross the body mid-line, and spread to terminate on the surface of the opposite midbrain tectum. Their synaptic arborisations become laid out in the tectum to form an accurate neurological map of the retina, orientated in rough alignment with the visual field of the eye concerned. Surgical disturbance of the growing visual pathway has little effect on the disposition of the map which optic nerve fibre terminals

Fig. 1 *a*, Scanning electron micrograph of the cut central stump of the optic nerve in a cichlid fish, *Astronotus ocellatus*. The arrow (u) points to the unmyelinated fibre edge of the ribbon (compare Fig. 2*a*), and *t* is the ribbon thickness, $\sim 100 \mu\text{m}$. *b*, Lengths of the left and right optic nerves from *Astronotus*. Both are desheathed, and the ribbon of one has been spread out flat. The arrow is the direction of fibre growth (*l*), and *w* is the width of the spread ribbon, here $\sim 7 \text{ mm}$. *c*, Transmission electron micrograph of a part of a ribbon optic nerve (*Tilapia* sp.). It comprises myelinated fibres exclusively in this region. Ribbons from different sized fish are roughly equal in thickness ($t = 75 \mu\text{m}$) but vary widely in width to accommodate up to 80,000 myelinated fibres.

establish in the brain, and this finding¹ has suggested that retinal axons are guided into their synaptic array by specific affinities for predetermined loci in the tectal surface¹⁻⁴.

Nevertheless, common sense suggests that mechanical constraints to axonal growth, like neighbour contact and substrate guidance, may also contribute to the normal development of spatial order in the tectal map⁵. How they might do so is easily seen from the normal mode of retinal fibre growth within the eye. The majority of ganglion cells destined to connect with the brain accumulate serially throughout life^{6,7} in retinal tree rings, by cell division around the iris margin of the eye⁸⁻¹⁰. Thus, new optic neurites continually extend inwards from the retinal circumference to the head of the optic nerve, growing alongside their neighbours and over a template surface formed by previously differentiated axons and their satellite cells.

My purpose here is to establish whether neighbour relationships between retinal axons, laid down in the eye^{11,12}, are normally preserved throughout the remaining course of the visual projection to the tectum. To answer this question, and to understand the topological continuity of the visual pathway, I studied an informative optic nerve structure (Fig. 1*a*)^{13,14} found in certain fishes (many of the Cichlidae, and various other percoid fish). Visual axons are laid out in the cross-section of this nerve to form an accurate map of the retina¹⁴. I will show that the map is of a strikingly simple form which suggests that it is shaped by very short-range constraints (such as physical contact) to the growth of single fibres. However, at a definite point along the length of the optic nerve, almost at its central end, the map becomes topologically re-ordered in a manner which involves systematic neighbour exchanges between fibres, and therefore can only be mediated by some longer-range mechanism of guidance. I will argue that this re-ordering—the only fibre manoeuvre in the normal projection which manifestly requires long-range guidance—must also be a general feature of other lower vertebrate retinotectal pathways. Moreover, both the nature of the re-ordering, and the fact that, as discussed later, it is apparently completed before fibres arrive at the tectum, seem to preclude that its mechanism involves adhesive axonal recognition^{1,4,15} of loci within the tectal surface.

Retinotopic maps in ribbon optic nerves

Figure 1*a* shows the cut central stump of the optic nerve in a cichlid fish. Within a cylindrical outline, it contains a folded

internal ribbon of nerve fibres¹⁴, easily flattened out into a continuous sheet (Fig. 1*b*). Apart from one edge, whose relatively small cross-sectional area is filled by numerous (up to 25% of the total) closely packed fine unmyelinated fibres, the ribbon comprises myelinated axons only (Fig. 1*c*). The myelinated fibres are laid out in the cross-section of the ribbon to form an accurate map of the retinal surface, but one whose topology is not directly related to the circular outline of the eye. Instead, as shown below, the polar coordinates of the retina become laid out orthogonally in a Cartesian fibre map which is bounded by the rectangular (though folded) cross-section of the ribbon.

Figure 2*a* shows the layout, in the nerve, of (degenerating) axons from a dorsal sector of the retina, distributed as a thin continuous sheet¹⁴ throughout most of the width (*w*) of the ribbon, and accurately located halfway through its thickness (*t*). These degenerating fibres were severed inside the eye by a small cut through the retina, close to the optic disk, and parallel to the circumference of the eye, which interrupted a sector-shaped beam of peripheral dorsal retinal axons. Retinal lesions of this sort always produced sheet-like degeneration patterns extending from the unmyelinated edge of the ribbon through some fraction of its width directly related to the area of retinal surface whose fibres were severed. Thus, the *w* axis of the ribbon maps the retinal radius, with equal increments (Δw) representing retinal annuli of roughly equal area. The myelinated edge of the ribbon is the origin (w_0), representing the centre of the retina. This suggests that the unmyelinated fibres, numerous though they are, represent a queue waiting for consolidation into the extended myelinated ribbon of an older fish. In agreement, their degeneration patterns (detectable only by electron microscopy) extend those in the rest of the ribbon, and they comprise, as growth proceeds, a diminishing fraction of all axons in the nerve. If it is assumed that the rate of addition of new retinal cells during growth is roughly constant^{1,2}, then equal increments to the width of the myelinated part of the ribbon (for example, Δw in Fig. 2, and see below) represent equal growth periods.

Conversely, and contrary to an earlier analysis¹⁴, radial sectors of the retina are mapped in circumferential order, across the thickness (*t*) of the ribbon. The ribbon's two surfaces, boundaries for this linear representation of the eye circumference, correspond with a radial and ventral discontinuity in the otherwise closed outline of the retinal disk. This is the embryonic choroid fissure¹², which persists throughout adult life in

fishes with ribbon nerves. Axons from retinal cells along each edge of the fissure are guided to run along one or other surface of the ribbon (Fig. 2b).

Fig. 2 Transverse sections of ribbon nerves, showing osmiophilic myelin degeneration patterns which result when populations of axons from narrow sectors of the retina are severed close to the optic disk. The sectors were mapped in animals killed after 3–4 weeks survival. Primary fixation was with aldehydes in 0.3M buffer with added divalent cations, followed by OsO_4 then epoxy embedment. The light micrographs are of unstained 2–5- μm sections, with the ribbon outlines emphasised by pen. Parts *a* and *b* are before the chiasm, and *c* and *d* beyond it. *a*, Right eye ribbon from the cichlid *Aequidens maronii* after severing a 30° sector of dorsal retinal fibres (compare positions 2–3 in Fig. 3). Degeneration debris (arrows) forms a sheet halfway through the thickness (*t*) of the ribbon, which could only be followed into the unmyelinated region (*u*) by electron microscopy at shorter survival times. Δw matches part *d* of this figure, and the scale bar is 50 μm . *b*, Similar ribbon (*Tilapia* sp.) where a retinal lesion interrupted fibres from the temporal edge of the choroid fissure (position 4, Fig. 3). Myelin debris is located along the corresponding surface of the ribbon. Scale bar, 50 μm . *c*, Part of the same ribbon as in *a*, cut further upstream almost at the left tectum, and viewed in the direction of fibre growth. Because the nerve has now wrapped around the ventral and contralateral surface of the brain, the unmyelinated edge of the ribbon (*u*) faces dorsolaterally (upwards here) rather than ventrally as at the exit from the eye (compare Fig. 3). Degenerating fibres still form a sheet. The numbered boxes define the position in the nerve of the fibre strips depicted in Fig. 4, and refer also to Fig. 3. Scale bar, 50 μm . *d*, The same ribbon approximately 70 μm closer to the tectum, at a location intermediate between the two numbered levels of the projection depicted in Fig. 4. The sheet of fibre debris has separated into blocks, one to each ribbon cross-lamina (lines), which are exchanging position with fibres at the lateral surface of the ribbon. Δw contains the same number of fibres as in *a*, showing the relationship between the fibre map grain and the size of the cross-laminae.

Changes in the outline of the fibre map

The extension of the ribbon, which I define as the ratio of width to thickness (w/t), varies along the length (l , Fig. 1*b*) of the optic nerve, having its smallest value ($w/t \approx 5$) where retinal axons leave the eye through the apex of the choroid fissure as a broad vertically orientated strap, not yet folded up. Extension rises to remarkable values ($w/t \approx 200$; $w > l$) in older fish as the ribbon folds up shortly behind the orbit. It condenses again to between 10 and 20 where the optic nerves cross (bodily) at the mid-line and approach the contralateral tecta. But retinal fibres remain in constant positions relative to w and t throughout, almost to the tectum, so these changes of outline are fluid deformations, only minimally affecting the local neighbour relationships of fibres within the ribbon (compare Fig. 2*a* and *c*).

In principle, the more radial transformation between circular retinal topology and the layout of axons within the nerve could arise by a process of fluid deformation similar to that involved in ribbon extension and condensation. This is most easily seen in the following way. Imagine the retinal disk is a fan, opened through 360° so that its edges meet at the position of the ventral choroid fissure. Now picture closing the fan. This manipulation compresses retinal points into an internal order similar to that assumed by corresponding fibres in the ribbon. If allowance is made for the fact that the ribbon maps the retinal radius as r^2 rather than linearly, the description below, summarised in Fig. 3, shows that axons enter the optic nerve in a projection pattern broadly isomorphous with this model transformation, which resembles a conformal mapping¹⁶.

The retinal projection into the optic nerve

In retinal whole mounts, axons of ganglion cells recently added in the periphery are seen clearly to run over the outer, vitread, surface of older established fibres, and they converge radially upon the most ventral edge of the ribbon as it leaves the eye. The more centrally the fibres originate, the more deeply they are stratified in the layer of retinal axons and the more their course is directed towards the dorsal apex of the slit-shaped optic disk. These points, true also in embryonic chick retina¹¹, are shown schematically in Fig. 3. The diagram shows how retinal fibres project into the ribbon outline without changing their local neighbour relationships; to verify that this is so, account must be taken of fibres of retinal eccentricities between the two extremes depicted (*c* and *p*).

This interpretation suggests how retinotopic order in the nerve could be generated by rather minimal physical constraints to the growth of new fibres extending from the retinal margin. Sufficient growth rules could be that individual neurites, (1) can only extend over a substrate formed by their predecessors in differentiation, and (2) cannot freely exchange neighbour relationships with others growing at the same time.

Fig. 3 A schematic picture of how fibres from an extreme peripheral annulus of retinal ganglion cells (*p*) and an extreme central one (*c*) project into the cross-section of the ribbon nerve as it leaves the right eye (viewed as if through the pupil), yet to extend and fold into the outline shown in Fig. 1*a*. Along each retinal radius, axons originating between these two extremes are ordered in the depth of the fibre layer according to eccentricity and take intermediate courses to the head of the nerve. Nasal, dorsal, temporal and ventral retinal quadrants are N, D, T and V respectively, and *f* is the choroid fissure. Numbered circumferential positions refer to Figs 2*c* and 4.

Mature patterns of axonal fasciculation in the cichlid retina and nerve, as elsewhere^{11,17}, involve frequent local exchanges between nearby fibres. If these exchanges were cumulative, it is arguable that any nascent retinotopic order should become scrambled before axons reach the brain, but degeneration patterns in the nerve show no signs of diffusing. Fasciculation patterns must, therefore, represent entirely local segregations of fibres into bundles—a kind of random bracketing which could well be mediated by glial ensheathment and continued tissue growth.

How fibres leave the ribbon

Cartesian retinotopic order persists throughout almost the entire length of the ribbon (Fig. 2a, c), to the point where its outlines begin to merge into the marginal fibre brachia of the contralateral tectum. This prompted the question whether considerations shaping the form of the fibre map also play a part in the accurate assembly of optic axon terminals into the visual map on the tectum itself. First of all, does the fibre map in the ribbon unfold again conformally like a fan, during radiation onto the tectum, as it became folded (Fig. 3) at the optic nerve head? The short answer is no.

Just before (150–300 μm) the folded outline of the ribbon coalesces into the tectal brachia, its entire width (w) sub-divides into a series of cross-laminae, each comprising a few hundred fibres. The laminae have very sharp boundaries, visible in thick sections of normal nerves as shearing planes which separate countercurrents of fibres running extremely obliquely in opposite directions across the thickness (t) of the ribbon. Within laminae, however, fibres change their positions in the ribbon by more fluid movements, for the most part preserving neighbour relationships.

Particularly for axons at the lamina boundaries, these manoeuvres abruptly disrupt neighbour relationships between fibres, otherwise preserved throughout the entire retinotectal projection. Their major effect is to re-order, piecewise, the fibre map of the eye circumference laid out across the t axis of the ribbon. The movements are illustrated in Fig. 2c and d, showing how degenerating fibres from a dorsal retinal lesion, first ordered in a continuous sheet (Fig. 2a, c), separate into blocks and move onto the lateral surface of the tract (Fig. 2d). Figure 4, compiled from similar data for other retinal sectors, shows schematically how all fibres within a single cross-lamina (representing a retinal annulus) become re-ordered by these exchanges, which were identified many years ago in the roach¹⁸.

Because axons in each lamina of the ribbon move independently in the same way, the outcome is to reverse the handedness of the entire fibre map, and to re-allocate its boundaries to a new point on the eye circumference. Handedness here means the direction, relative to the growth axis (w), in which the eye circumference is mapped across the thickness of the ribbon (t). To specify handedness, a viewpoint must be defined, and the natural one, adopted in Figs 2 and 4, is the direction along which fibres grow and conduct impulses. As visual fibres originate on the outer surface of the retina, this convention dictates that the layout of ganglion cells be viewed, as in the keys to Fig. 4, from behind the eye. Thus, Fig. 4 shows that, in an otherwise continuous projection, a coarse-grained reversal of map handedness at the cross-laminae enables fibres to proceed to their tectal loci without further exchange of their neighbour relationships.

Irrespective of retinal eccentricity, established myelinated fibres complete their re-ordering together within a very short distance (for example, 200 μm) compared with the pathway length (for example, 1 cm) accrued by bodily growth since the first embryonic fibres arrived at the tectum. Thus, although it was not possible to trace, by degeneration methods, the small minority of unmyelinated fibres engaged in growth at any instant, extrapolation suggests they also re-order at the same level.

Fig. 4 Schematic interpretation of how retinal axons within a single cross-lamina of the ribbon nerve become internally re-ordered as they approach the rostral (R) pole of the left tectum. The strips represent blocks of axons from different sectors of an annulus of ganglion cells in the right retina, numbered and labelled as in Fig. 3. Their starting configuration corresponds with the numbered blocks superimposed on the micrograph of Fig. 2c. Fibre populations in each cross-lamina of the ribbon (compare Fig. 2d) re-order independently and in the same way. Each maps an increment (Δw , Fig. 2a and d) of the retinal radius. Accordingly, the black surfaces of the strips are fibres most recently added to the cross-lamina, depicted rather conjecturally as they could not be traced fully. The course of the strips onto the tectal map is consistent with the fibre radiation pattern seen in whole mounts, although the twist handedness depicted for strip 1 is arbitrarily chosen. The keys on the left are back-projections of the lamina to its origin in the right eye (shown as if viewed from behind) to show how re-ordering reverses the circumferential sequence (arrows) of the fibre map, and re-allocates its boundaries (gaps) to a nasal position. M, C, L, and R are medial, caudal, lateral and rostral poles of the tectum respectively; other labels as in Figs 2 and 3.

Other retinotectal projections

It is important to realise that the cross-laminar fibre re-ordering in the cichlid ribbon is not related to any basic mismatch of handedness between retinal image and tectal map. They are, as in other lower vertebrates, superimposable when properly viewed from a single frame of reference, for example the standpoint of axonal growth. It relates instead to a general mismatch between the orientation of the tectal map and the direction of optic tract approach. This is best understood from Fig. 4 by noting that the positional exchanges depicted would be unnecessary were the pathway to approach the tectum medially rather than rostrally.

Because the mismatch is a consequence of the relative layout of the tract and the tectum, it must be a general characteristic of other lower vertebrate retinotectal pathways, which the cichlid projection resembles in all particulars except the unusual ribbon structure of its optic nerve. Data in the literature make it possible to state this argument more explicitly. In amphibia, the axis along which new fibres accrue to the optic tract²¹, and the direction through which the tract approaches the tectum, are the same as in the cichlid pathway at a comparable level. Moreover, orthogonal to the growth axis of the optic tract, amphibian visual fibres are laid out in a retinal circumferential sequence (NVTDN, Fig. 4)²² matching that into which cichlid axons

emerge from the ribbon cross-laminae (Fig. 4), similarly bounded and of the same handedness. As the arrangement is of opposite handedness to the layout of retinal fibres as they originate in the eye (Fig. 4, keys), some reorganisation of the fibre map similar to that achieved in the cichlid cross-laminae must already have been mediated before the amphibian optic tract emerges onto the lateral wall of the diencephalon, possibly as far downstream as at the optic chiasm. Indeed fibre interdigitation patterns in fused chiasms have a certain resemblance of appearance to the cross-laminae located further upstream in the visual pathway of cichlids, whose optic nerves, as in fish generally, cross bodily at the mid-line.

Conclusions

It is hazardous to infer prior developmental mechanisms from differentiated structures. Within their limits, however, these observations allow certain useful conclusions. First, an extremely short-range mechanism, possibly no more sophisticated than physical contact between adjacent retinal axons, is evidently consequential enough to determine the layout of optic nerve fibres throughout most of their course to the tectum, albeit a layout incompatible with that which their axon terminals must adopt in the tectal map. Second, the topological re-ordering necessary for axons to reach their correct terminal sites in the tectum involves neighbour exchanges and must, therefore, be

guided by longer-range constraints to fibre growth. This re-ordering, which I have argued must be a general feature of lower vertebrate retinotectal projections, seems to be mediated, particularly in Amphibia, some distance before growing fibres reach the tectum. It is unlikely, therefore, to be the outcome of exploratory axonal growth towards putative neuronal recognition sites within this tissue. Finally, the piecemeal nature of the re-ordering means that the number of retinal fibres which exchange their neighbours is, in fact, a small fraction of the total. It can be seen, therefore, that the mechanism which guides re-ordering of the fibre map needs in principle only to act on a fraction of the fibres which are involved in the movements; the rest might follow by neighbour guidance.

Current understanding of the ontogeny of the retinotectal projection is that the accretion of new retinal fibres is a continuous process^{7,23,24}. One urgent question raised by the findings described here is how the continual growth of the pathway is punctuated to enable the large blocks of fibres, comprising single cross-laminae (Δw , Figs 2 and 4), to reorganise as independent units.

I thank the Electron Microscopy Unit at Queen Mary College, London, and particularly Dr P. Mobbs, for making scanning micrographs and Dr W. Lieb, Professor B. B. Boycott FRS, Dr D. S. Gilbert, and Christine Holt for critically reading the manuscript, and for their helpful suggestions.

The accuracy of predicted radioastronomical frequencies and the spectrum of hydroxyl

IF radioastronomers are to use predicted frequencies to search for new interstellar species, they require some fairly precise indication of the accuracy of the theoretical calculations. Calculations of rotational constants are not very accurate by the standards of radiofrequency spectroscopy, but computations of Λ -doublet splittings have seemed remarkably accurate¹⁻³. However, these calculations were presented without error limits and as it is not possible to produce these from pure theory we have used the hydroxyl radical to probe the limits of accuracy. The experimental frequencies are known from observations^{4,5} of the interstellar maser action in OH to a high precision, and it is a particularly suitable case for computation. We show here that the prediction for the lowest rotational level is accurate to 1 MHz; an accuracy higher than conventional terrestrial experimental spectroscopy.

By considering Λ -doubling of rotational levels of $^2\Pi$ states to be caused by second order perturbations, Van Vleck⁶ showed

that the splitting may be expressed in terms of the parameters $(\frac{1}{2}p+q)$ and q :

$$\Delta\nu = -(\frac{1}{2}p+q)[1 \pm (2-Y)/X](J+\frac{1}{2}) \mp (2q/X)(J+3/2)(J+\frac{1}{2})(J-\frac{1}{2})$$

Here the upper signs refer to F_2 sublevels and the lower to F_1 ;

$$X^2 = Y(Y-4) + 4(J+\frac{1}{2})^2 \quad \text{and} \quad Y = A_v/B_v$$

The parameters p and q depend on integrals over vibronic wave functions of the operators $\hat{B}(\hat{L}^+ + \hat{L}^-)$ and $\hat{H}_{so}$. These matrix elements are factorised into vibrational and electronic integrals so that the contribution of a single $^2\Sigma^+$ electronic state to the splitting in the v th vibrational level of a $^2\Pi$ state is given by

$$p_v = 4 \langle ^2\Pi | \hat{H}_{so} | ^2\Sigma \rangle \langle ^2\Pi | \hat{B}(\hat{L}^+ + \hat{L}^-) | ^2\Sigma \rangle \times \sum_v \frac{\langle v | \hat{B} | v \rangle}{E_{v,v} - E_{\Sigma,v}}$$

and

$$q_v = 2 \langle ^2\Pi | \hat{B}(\hat{L}^+ + \hat{L}^-) | ^2\Sigma \rangle^2 \sum_v \frac{\langle v | \hat{B} | v \rangle^2}{E_{\Pi,v} - E_{\Sigma,v}}$$

Fig. 1 Λ -doubling ($\Delta\nu$) in the lowest rotational level of OH ($^2\Pi_{1/2}$; $J=3/2$) showing the observed radioastronomical transitions in MHz (not to scale).

where the summation should be taken over all vibrational levels, v' . Contributions from all $^2\Sigma$ states are then added with $^2\Sigma^-$ states giving negative terms.

An earlier study¹ calculated p and q for OH assuming that molecular orbitals were invariant between electronic states and restricted summations by assuming Van Vleck's case of pure precession. Here we have calculated separate wave functions for $X^2\Pi$ and $A^2\Sigma^+$ using Cade and Huo's atomic orbital basis set⁷ in the ALCHEMY program⁸. The electronic functions were then improved by configuration interaction (CI) using 15 Π configurations and 11 of Σ symmetry. This was done in stages to ensure that a limit had been achieved; further additions did not change the computed values of p and q .

Morse functions were used for vibrational wave functions after showing that these give identical results to those obtained with numerical solutions from RKR curves. The vibrational summations over v' extend to $v'=5$; terms for $v'=5$ and above do not contribute significantly.

The effects of $B^2\Sigma^+$ were calculated to be less than those of $A^2\Sigma^+$ by a factor of about 10^9 , indicating how good Van Vleck's pure precession approximation is in this case.

Figure 1 indicates the observed astronomical transitions with epicentres separated ($\Delta\nu$) by 1,666 MHz. Table 1 shows calculations of p and q and of this separation.

This lowest rotational level is the one of prime importance astrophysically and the agreement between theory and experiment is essentially exact, being better than 1 MHz. However, the splitting in this particular level depends mostly on the value of the constant q . A slightly more difficult case for theory is provided by the manifold excited rotational states, where p as well as q has an influence and errors are magnified by multiplication of the constants by higher powers of the rotational quantum number.

Table 1 Λ -doubling in the $X^2\Pi$ ($v=0$; $J=3/2$) state of OH

	p (cm^{-1})	q (cm^{-1})	Splitting (MHz)
Hinkley <i>et al.</i>	0.242	-0.0391	
This work without CI	0.2308	-0.03807	
This work with CI	0.2378	-0.03982	1,666
Terrestrial expt	0.2348	-0.0387	1,654
Astronomical expt			1,666

For $J=1/2$ of $^2\Pi_{1/2}$ the separation of epicentres of the observed astronomical lines is 4,730 MHz, for which our calculations predict, 4,795 MHz; $J=5/2$ of $^2\Pi_{3/2}$ has a terrestrially measured separation of 6,033 MHz and we calculate 5,946 MHz, whereas the even more highly excited level $J=5/2$ of $^2\Pi_{1/2}$ has an epicentre separation of 8,153 MHz and our result is 8,444 MHz.

These results suggest that the realistic limits for our calculations, if done with care, are a few megahertz. This is better than conventional spectroscopy. We intend to recompute the Λ -splitting in SiH to this accuracy so that calculations of this type can be used to predict as yet unobserved interstellar molecules and ions.

The computational work was supported by a grant from the SRC and forms part of a project supported by a NATO research grant.

A nonspherical thermal instability in young stars

NONSPHERICAL thermal instabilities have been shown¹⁻⁴ not to be excited during the hydrogen-burning phase of stellar evolution. However, this conclusion holds true only for models with a homogeneous distribution of heavy elements. We show here that in nonhomogeneous young stars more massive than, or of the same mass as, the Sun, large-scale nonspherical thermal instability can be excited during the short period of time when carbon just starts capturing protons but before convection has set in.

The non-homogeneous structure is expected to form in the case of a dusty protocloud. In this case gravitation can collect the dust at the centre of gravity of the cloud^{5,6} or the dust can fall into the centre during cloud contraction⁷. We assume here that, although heavy elements are concentrated near the centre, their mass fraction (Z) is small everywhere and Z is proportional to Z_{12} , the mass fraction of carbon. Convective mixing of the central region before the ignition of nuclear reactions is assumed not to occur. This is true if the mass of the star is sufficiently large⁸⁻¹⁰. For simplicity, effects due to rotation and radiative pressure are ignored in the following.

For thermal instability to occur ϵ , the rate of nuclear energy generation, must be highly sensitive to T , the temperature. We take ϵ to be proportional to $\rho X Z_{12} T^\nu$, where ν is assumed to be constant. The dependence of ϵ on Z_{12} makes this sensitivity greatly enhanced in our case of a small Z , that is, of large h_μ/h_Z , where μ is the molecular weight, while scale height $h_\mu = -(\partial \ln \mu / \partial r)^{-1}$, and so on. (Here $h_\mu > 0$, and $h_Z > 0$, but h_X is likely to be negative.) In other words, for this rapidly growing instability any displacement leads to a change in mass fraction of heavy elements which is much larger than, and of the same sign as, the change in molecular weight. Furthermore, the excitation of the nonspherical thermal instability leads to negligibly small distortions in pressure and density distributions, we find¹⁻⁴ that

$\mu^*/\mu = T^*/T$, that is, the relative eulerian perturbations of molecular weight and temperature are equal. Thus, provided that the time of instability growth is much shorter than the timescale of change of the unperturbed energy generation rate, we find that a large increase (decrease) in this rate corresponds to a small increase (decrease) in the temperature. This conclusion follows from an equation^{2,4} generalised to include variations in $Z_{12} = \text{const}$. Z :

$$\varepsilon^* T (\varepsilon T^*)^{-1} = \nu_{\text{eff}} = \nu + h_\mu (h_Z^{-1} + h_X^{-1})$$

As $h_X \approx h_\mu$ and $h_\mu \gg h_Z$, we have $\nu_{\text{eff}} \approx h_\mu/h_Z$. Usually, $\nu \approx 15$ – 20 , while Richstone's⁴ estimate shows that some mean value of $\nu_{\text{eff}} \approx 20$ makes the nonspherical thermal instability likely. If Z equals a few per cent then $\nu_{\text{eff}} \approx 100$. Such a value of ν_{eff} is so large that the probability of instability excitation is high even though, in our contracting model, most of the energy liberated is due to the contraction of the model. This instability excitation certainly occurs in models with a sufficiently large mean value of ν_{eff} , in which case the perturbed opacity can also produce a destabilising effect. For the most rapidly growing perturbation, the point of the highest temperature is displaced while the distributions of pressure and density remain almost unaltered.

Here we are considering the phase of evolution before the formation of the convective core; this means that f , the radial component of unperturbed entropy gradient, decreases and tends to zero. Therefore, rapid motions should be excited to ensure the necessary change in entropy to fulfil the energy balance in the perturbed state, which is characterised by almost the same entropy distribution as the unperturbed state. In other words, the time of growth can be very short in the model under consideration^{2,4}. The minimum value of the time of growth (τ_{min}) is determined by when perturbations of pressure and density fields become significant. This gives $\tau_{\text{min}} \approx (r^2 \varepsilon^{-1} h_p h_Z h_*^{-2})^{1/3}$, where $h_* = |\nabla \ln p^*|^{-1}$. It is easy to take the time dependence of τ into account if f can be modelled by a linear function of time.

Detailed computation is necessary to find that mean value of h_μ/h_Z above which a rapidly growing instability is really excited in the model chosen. When $\nu_{\text{eff}} \approx 100$, the instability apparently does exist in many models. Using Iben's¹¹ models of contracting stars we find that time τ_{min} is usually of the order of 0.1 yr. As the molecular weight of each moving elementary volume is conserved, we expect, as a result of the instability, that large-scale relative spatial variations $T^*/T \sim \mu^*/\mu \sim h_p/h_\mu$ are formed, whereas $v_r^* \sim h_*/\tau$, and $p^* \leq r^2 \rho/\tau^2$; for a $3M_\odot$ model, $v_r^* \sim 10^4 \text{ cm s}^{-1}$, and $p^*/p \leq 10^{-7}$, the nonspherical motions produced by the instability are large enough to transfer all the heat produced by the energy source. Also, these motions can effectively amplify the magnetic fields which are expected to be present in young stars. A field-induced instability followed by emergence of frozen-in fields on the surface can be responsible for the erratic activity usually observed in young stars.

Considering outbursts in FU Ori type stars¹², an interesting model would be one undergoing recurrent phenomena involving a temporal increase of the energy generation rate by more than two orders of magnitude on a scale of some months. If this increase were caused by the nonspherical thermal instability excited at the moment when the equilibrium is nearly adiabatic, then the time of growth can be as short as a month. However, to ensure that ε increases we have to accept that the instability can lead to the formation of a nonspherical structure containing points at which the temperature is up to 1.5 times higher than the unperturbed temperature. In this case the unperturbed model must have a large central concentration of heavy elements. More thorough study is needed to clarify whether such a model can be unstable. If the instability is possible, and its excitation produces large variations in the temperature field, the pressure field will also be disturbed. In such circumstances local convection is likely in some regions with the convective heat flux depending on the horizontal coordinate. If periods of liberation of considerable energy are followed by the energy source zone

expanding slightly at the same time as local convection reduces due to the horizontal temperature differences, then the contraction phase which was terminated by the instability excitation can resume. In this rather speculative sequence of recurrent outbursts, the local convection (perhaps coupled with the magnetic field induced instability) is supposed to be effective in transporting heat but not in causing full mixing of the energy source zone.

Nuclear reactions seem to maintain and amplify the horizontal temperature variations of the type in question¹³. That is because the ratio T/μ remains spherically symmetric, the temperature and hence the nuclear burning rate are higher within those regions where the burning element is more exhausted and, hence, the molecular weight is larger. Thus, we cannot exclude the possibility that the structure with the horizontal temperature variations can survive the stage of hydrogen burning at least in models not having convective cores, or in models where the convection is modified (in the presence, for example, of a magnetic field) to such an extent that the convective mixing does not destroy the horizontal variations mentioned. I have suggested elsewhere that a similar state is realised in magnetic stars¹³, in which case, the dimensions of the model seem to be larger and, hence, the rotation to be slower. These facts apparently agree with the observational data¹⁴.

I thank the N. Copernicus Astronomical Center for hospitality, also E. Ergma and B. Paczyński for helpful discussions and D. S. Hall for language corrections.

Drifting spikes—a new species of solar radio bursts

OBSERVATIONS of solar radio bursts of spectral type IV have revealed the presence of a complicated fine structure in the emission at metric wavelengths^{1–4}. It would be interesting to extend high resolution spectral observations to decimetric wavelengths to explore the structure of radiation which is generated at lower heights in the solar atmosphere, and is, therefore, closer to the site of the associated optical flare. We report here a new species of fine structure bursts, drifting spikes, which have been observed in the 500 MHz frequency region.

A radio spectrograph covering frequencies $490 \leq f \leq 550$ MHz has been in operation at the Oslo Solar Observatory since 1972. The instrument sweeps across the observed band at a rate of 50 times per s, and has a frequency resolving power of 0.3 MHz.

Drifting spikes were recorded on 18 September 1974, 11.14–11.17 UT, 23 September 1978, 10.14–10.18 UT and 27

Fig. 1 Dynamic spectra showing drifting spikes observed at: *a*, 18 September 1974; *b*, 23 September 1978. Time marks, each lasting for 1 s, are seen as weak horizontal dashes. They occur at frequencies separated by 5 MHz.

September 1978, 14.45–14.47 UT. In all cases type IV bursts were in progress and flares of importances 2N, 2B and 2B showing two-ribbon structure were observed in H α at the respective times.

Simultaneous observations with radio spectrographs in the bands 140–170 MHz and 310–340 MHz revealed no drifting spikes. But bursts of this type were present on records obtained with the Dwingeloo radio spectrograph on 23 September 1978. The instrument was then tuned to cover the bands 509–533 MHz, 574–614 MHz and 655–666 MHz. The phenomenon may thus be typical at decimetric wavelengths. It is not known whether drifting spikes appear at even shorter wavelengths.

Two examples of drifting spikes are given in Fig. 1 which shows that a large number of tiny bursts are superimposed on a smooth continuum emission. Each elementary burst has a short duration, narrow bandwidth and a frequency drift from higher to lower frequencies.

Several parameters typical of individual bursts were measured on the record from 23 September 1978, which contained the

Fig. 2 The definition of some relevant burst parameters in the time-frequency plane: b_i , instantaneous bandwidth; b_o , frequency range (total range of frequency occupied by the burst at all times); d_f , duration at one frequency; d_o , lifetime (total duration of the burst at all frequencies). The slope of the burst is indicated by a dotted line, from which the frequency drift rate, df/dr , is determined.

most spectacular event. (Denotations in the following are as in Fig. 2.) The frequency range covered by single bursts (b_o) was small, the average value being 2.7 MHz. It was difficult to determine the instantaneous bandwidth b_i with good precision. Only an upper limit, $b_i \leq 1.5$ MHz can be determined. Thus drifting spikes are very monochromatic, $b_o/f = 0.5\%$ and $b_i/f \leq 0.3\%$.

For the lifetime, d_o , the average value was 0.12 s. Another quantity of interest is the duration at one frequency (d_f), but as most bursts were not adequately resolved with our sweep repetition rate of 50 Hz, it is concluded that $d_f \leq 50$ ms.

All spikes showed a frequency drift. The average value of df/dr was -23 MHz s^{-1} , giving $(1/f) df/dr = -0.04 \text{ s}^{-1}$. This is larger than, but of the same order of magnitude as, that found for intermediate drift bursts (fibre bursts) in the same frequency range. The scatter in burst slopes was surprisingly small, and positive drifts were not seen.

Drifting spikes frequently appeared as pairs at roughly the same frequency with the elements separated in time by 0.15 s. There was also a second and very distinctive type of ordering of the bursts. On the records they formed columns because drifting spikes were generated almost simultaneously at many frequencies separated by intervals of 5–10 MHz. This was demonstrated even more clearly by a comparison between our records and those obtained with the radio spectrograph at Dwingeloo. The effect is similar to that seen when stria bursts are ordered into decametric-type IIIb bursts.

Another important property was a regular repetition of the columns of drifting spikes. This is seen in Fig. 1b. The drifting spikes are generated at time intervals which have an average value of 1.2 s. It is interesting that before the occurrence of drifting spikes, the continuum intensity showed oscillations (pulsating structure).

If the emission frequency is equal to, or near to the plasma frequency, the occurrence of drifting spikes between 500 and 666 MHz implies electron densities $N_e = 3\text{--}5.5 \times 10^9 \text{ cm}^{-3}$ at the place of generation. New observations at higher frequencies may lead to an increase of the upper limit. The quoted electron densities correspond to heights below 50,000 km in active regions. Single frequency durations $d_f \leq 50$ ms are of the same order of magnitude as the electron collision time in these regions.

The phenomenon described here is of particular interest in connection with other observations of decimetric and centimetric fine structure^{5–7} and a theoretical discussion of mechanisms for the production of millisecond bursts. A possible quasi-periodic generation of such bursts by plasma turbulence in flare regions has been envisaged⁸.

Further explorations of the finest structures in solar radio bursts at short wavelengths may lead to the detection of basic, small scale acceleration processes in solar flare regions.

A comprehensive analysis of drifting spikes will be given elsewhere.

We thank Dr C. Slottje for the opportunity to inspect the Dwingeloo radio spectrograph records, also T. Engebretsen and B. Rygh at Oslo Solar Observatory.

Detection of circularly polarised light from noctilucent clouds

NOCTILUCENT clouds are very tenuous clouds that appear in the high latitude mesosphere during the summer¹. They are seen by scattering of sunlight from cloud particles near the mesopause. They are known to be at altitudes of ~82 km, more than 50 km higher than the next highest clouds in the atmosphere, the nacreous or mother-of-pearl clouds. They are usually seen after midnight in June and July in the north-east twilight arch at latitudes of 55–65° and appear silvery-blue² in the red twilight glow. Observations have been made from ground level^{3,4}, rocket⁵ and satellites^{6,7}. Studies of sunlight scattered from the clouds have concentrated on measurements of polarisation of the scattered light to allow estimates of the size distribution of the cloud particles to be made. These estimates agree in that only submicron particles with an upper radius limit in the range 0.05–0.3 μm are present. Recent measurements⁴ of scattered light have shown the presence of a small proportion of circular polarisation, indicating that the cloud particles are probably non-spherical, and estimates of the particle size, being based on the assumption that scattering is from homogeneous spheres (Mie scattering), may need revision. The revision might be enough to force reappraisal of the amount of water condensed to form the clouds and consequent reappraisal of the relative humidity in this part of the atmosphere. A small amount of circular polarisation can be produced in the scattering of natural (unpolarised) light from elongated particles⁸ but a greater proportion of circular polarisation will arise if the incident light is partly polarised and if the axes of the elongated particles show some directional preference. However, light scattered from spherical particles will also show some small amount of circular polarisation, if the incident light were to be linearly polarised in a direction skewed with respect to the plane of scattering. If the circular polarisation is produced by elongated cloud particles, it is possible that polarisation of the scattered light will show marked differences from place to place due to different proportions and directions of alignment of particles being caused by

updraughts or vertical wind shears present in different parts of the cloud region. This would not be expected if the circular polarisation was due to scattering of linearly polarised light from spherical particles. Apart from early photographic observations³, recent measurements of the polarisation in noctilucent clouds have been photo-electric and there has been no simultaneous measurement at different points spread over an appreciable part of the cloud display. We have developed and report here a method which allows us to test how circular polarisation varies over the area of display⁹.

A fixed-polariser/rotating-retardation plate assembly was placed in front of a sensitive television camera (with a silicon-intensified target (SIT)), fitted with a 25 mm, $f/0.78$ lens with blue-green filter. The period of rotation of the retarder was 24 s. The polariser and retarder were Polaroid thin-sheet (cellulose acetate butyrate) and allowed wide field viewing; the SIT photocathode gave a field of view of $22^\circ \times 29^\circ$ horizontally. The noctilucent cloud images recorded on videotape can be analysed on playback using a video-integrator¹⁰ which allows the sum of video signals from any area selected in the television field of view to be displayed on a chart recorder. The amplitude of the signal is proportional to the average light intensity in the selected area.

Analysis of the video signal is best handled using Stoke's vector to describe the state of polarisation of light from the noctilucent clouds. The Stoke's vector consists of a set of four components (the Stoke's parameters I , M , C and S). Each parameter is a time-averaged intensity: I is the light intensity; M contains the 'horizontal preference' of the polarised part of the light, C the '45° preference' and S the 'circular preference'. These parameters may be written as a column vector and the transmission of polarised light through the Polaroid/retardation plate assembly is estimated using Mueller calculus¹¹. The state of polarisation of the light emerging from the Polaroid/retardation plate combination is found by successive multiplication of the Stoke's vector of the incident light by the two matrices representing the Polaroid and the retardation plate. The intensity I of light falling on the television camera varies with time such that

$$I(t) = X + Y \sin 4(\beta(t) + \beta_0) - Z \sin 2\beta(t)$$

where $\beta(t)$ is the instantaneous angle between the fast axis of the retarder and the (fixed) polariser axis. If the Stoke's parameters

Fig. 1 Noctilucent cloud display seen from Aberdeen on the night of 28–29 July 1978. The print is from a monochrome copy of a 15-s ($f/2.8$) exposure on high-speed Ektachrome film. White lines enclose an area of sky where circular polarisation was detected.

of the light from the clouds are I_0 , M_0 , C_0 , S_0 , the expression for $I(t)$ contains the following:

$$\beta_0 = \frac{1}{2} \tan^{-1} (M_0/C_0);$$

$$2X = (k_1 + k_2)I_0 + \frac{1}{2}(k_1 - k_2)(1 + \cos \delta)M_0;$$

$$Y = (1/4)(k_1 - k_2)(1 - \cos \delta)(M_0^2 + C_0^2)^{1/2} \quad \text{and}$$

$$Z = \frac{1}{2}(k_1 - k_2) \sin \delta S_0$$

k_1 and k_2 are the principal transmittances of the polaroid; the retardance of the retarding plate is δ . In the simple case of partly polarised incident light which contains no circular polarisation ($S_0 = 0$), the video signal is a constant level X with a superimposed 4β sinusoidal modulation of amplitude Y . Addition of a small amount of circular polarisation ($S_0/I_0 \approx 0.01$) has the effect of adding in a 2β modulation on top of the 4β modulation and the presence of this shows up mainly as a half-frequency modulation Y . If the light from the clouds is predominantly linearly polarised, with only a small amount of circular polarisation added, then the detection of circular polarisation is simple, as extrema of the 4β signal will alternate in size.

Figure 1 shows a picture of the sky taken during the noctilucent cloud display of 28–29 July 1978. The Sun is 11° below the horizon at an azimuth of 24° . The videotape recording indicates that the degree of linear polarisation increases systematically from the clouds to the right of Fig. 1 (scattering angles $< 20^\circ$) to those shown in Fig. 1 (scattering angles 20° – 50°) as is to be expected both from scattering theory and from all previous reports of polarisation measurements of noctilucent clouds. However, regions in which the maxima of the 4β signal alternate in size have been found only in restricted parts of the cloud display and one such area is indicated in Fig. 1. Figure 2 shows part of the chart record obtained when integrating the video recording in this area. The alternation in height of the maxima is clearly seen, and analysis of the data from Fig. 2 shows the proportion of circular polarisation, S_0/I_0 , to be 0.005 ± 0.0013 . This is less than that of earlier measurements⁴, when S_0/I_0 was estimated to be typically 0.05 in the blue part of the visible spectrum. However, the noctilucent clouds that were seen on this occasion from Aberdeen were unremarkable in brightness and development, and the observation night was towards the end of the useful season.

The presence of a noticeable amount of circular polarisation in only certain parts of the display (adjacent regions showing, as far as can be seen, none) shows the effect is not produced locally by tropospheric scattering or absorption even at the great zenith distance of that area showing circular polarisation. There is no reason that the part of the noctilucent cloud that does show circular polarisation should have this difference from other parts of the display at the same zenith distance. It is also difficult to reconcile the appearance of localised circular polarisation with its being caused by partly polarised light incident on spherical particles. The cloud enclosed by the lines in Fig. 1 is at a latitude of 64.5° (no allowance being made for refraction) and there the Sun is only 4.4° below the horizon. The sunlight shining on the cloud passes the sunset line at a height of over 60 km and there is negligible absorption in the direct path. Any linear polarisation in the illumination of the cloud must come from tropospheric scattering near the sunset line, from that part of the atmosphere below the direct solar rays.

The relationship between degree of circular polarisation and amount of asphericity of the particles scattering the light cannot be described easily without knowing the distribution of sizes and shapes among the cloud particles. However, some estimate can be made by assuming that the low-contrast (or Rayleigh-Gans) approximations⁸ are applicable and that only unpolarised sunlight is shining on the clouds. If the scattering particles are cylinders of length exceeding two light wavelengths ($1 \mu\text{m}$), circular polarisation of $S/I = 0.005$ will arise if the radius of all the particles is close to $0.01 \mu\text{m}$. Alternatively, there could be a mixture of 10% of cylinders with radii $0.04 \mu\text{m}$ in a cloud of otherwise spherical scatterers.

Fig. 2 Section of chart record made using a video-integrator on the area of sky indicated in Fig. 1. Note the depressed zero of the ordinate scale; the proportion of linear polarisation present is ~ 0.16 . The presence of a small amount of circular polarisation is shown by the alternation in height of the maxima.

Little is certain about the way in which ice crystals will grow in the low temperature and low pressure conditions near the mesopause. By analogy with the efficient screw-dislocation growth of crystals in the laboratory, it is possible that a significant proportion of the cloud particles will grow into needles rather than into spheres and this is certainly seen in the laboratory at low temperatures which are, however, much higher than the temperatures of noctilucent clouds. The fall speeds of needle-shaped crystals will be less than those of spheres. The amount of light scattered by a single particle increases very quickly as it grows in a supersaturated layer in the atmosphere. Spherical particles, however, will fall out of this layer more quickly than needle-shaped particles and so have less time for growing. It could be that there will be an aerodynamic advantage for growth of non-spherical particles relating to the spherical ones and that these non-spherical particles, being large, will individually scatter more light than the spheres and so seem to be relatively more important when observing the light scattered from a cloud.

The relative humidity of the atmosphere in the cloud region controls the optical thickness of the cloud that can form. Needle-like scatterers with their longer residence times and eventually greater relative sizes will give thicker (that is, brighter) clouds than spherical scatterers. For a given cloud brightness, the atmosphere does not have to be as wet with needles as with spheres.

Isotopically light carbon in diamonds from some kimberlite pipes in Lesotho

THIS study of the isotopic composition of carbon has been carried out on six diamond crystals from kimberlite pipes in Lesotho. One crystal came from the Kao pipe, one from the Liqhobong and four from the Kolo pipe. We consider here how their colour and location are related to their isotopic composition.

The Kao and Liqhobong kimberlite pipes are located in the highlands of the northern Lesotho where they cut through the thick basaltic lavas of the Drakensberg Beds^{1,2}. The Kolo pipe is situated in the lowlands of western Lesotho and it cuts through the shales and sandstones of the Beaufort series and the Karoo dolerites. Diamonds from these deposits are characterised by a large quantity of fragments and angular forms (up to 65% for the Kao pipe and 80% for the Liqhobong and Kolo pipes).

Generally among the crystals, rounded dodecahedra prevail^{3,4} but a tendency towards an increase of octahedral forms in the Liqhobong-Kao-Kolo direction is noticeable.

Table 1 A brief description of the diamonds and analytical results of isotopic composition of carbon

No.	Pipe	Brief description	¹³ C‰ PDB
1	Kao	A flattened rounded twin of dodecahedra, smoky, transparent fissured. Faces 110 are unevenly pitted. The lines of plastic deformation and traces of etching are observed. Weight 40.62 mg.	-4.6
2	Liqhobong	A fragment of a lemon-yellow transparent octahedron with triangular cavities and hillock of irregular or rounded shape on the relics of faces III. Weight 30.5 mg.	-20.5; -10.6
3	Kolo	An irregular intergrowth of 3 flattened colourless transparent octahedra with development of the curved dodecahedral surfaces. The surfaces are badly etched with cavities. The diamonds have several graphite inclusions. Weight 30.95 mg.	-16.2; -15.9
4	Kolo	A rounded badly elongated on L ₃ yellow-transparent dodecahedron with several cavities. Weight 30.95 mg.	-6.9
5	Kolo	A rounded flattened colourless dodecahedron with several graphite inclusions. Faces 110 are roughly pitted with some hillocks. Weight 30.81 mg.	-6.5
6	Kolo	A rounded flattened smoky dodecahedron. The faces are irregularly developed and have deep canals of etching. An inclusion of orange garnet is observed inside the crystal. Weight 50.83 mg.	-14.7; -15.1

Serial no. *	Crystal habit	Colour	¹³ C‰ PDB
1	Twin or rounded dodecahedron	Smoky	-4.6
2	Fragment of octahedron	Lemon-yellow	-20.5; -19.6
3	Intergrows of octahedra	Colourless	-16.2; -15.9
4	Rounded dodecahedron	Yellow	-6.9
5	Rounded dodecahedron	Colourless	-6.5
6	Rounded dodecahedron	Smoky	-14.7; -15.1

* The diamonds are described in the same succession as in the text.

Many of the stones are of different colours and varying intensity: for the Liqhobong pipe, yellow is dominant: Kolo diamonds are mostly smoky-grey whereas Kao diamonds are brownish. Most of the diamonds have black inclusions of graphite. A brief description of the diamonds which have been analysed is given in Table 1.

Analysis of the isotopic composition of carbon of the diamonds has been done by oxidation in a stream of oxygen on copper oxide. The relative contents of isotopes of carbon have been measured by a mass spectrometer (Varian MAT -230) with precision of $\pm 0.01\%$ ($\pm 0.1\%$). Analytical data in Table 1 are in values of ¹³C ($\pm 0.1\%$). Analytical data in Table 1 are in values of ¹³C (‰) which are deviations in ‰ of ¹³C/¹²C of samples with respect to ¹³C/¹²C of the PDB standard.

Table 1 shows that three of the six diamonds (nos. 2, 3 and 6) are characterised by somewhat light intermediate composition of carbon (group B of the Galimov *et al.*⁵ classification). Note that the analysis of these diamonds has been done twice and the data obtained have been rechecked.

Diamonds with a similar carbon isotope composition have not been reported either in kimberlite rocks of Africa^{6,7} or in Yakutia^{5,8}. Therefore, it had been thought until recently that the ratio ¹³C in kimberlites is rather constant and is characterised by a value ¹³C = -4 to -9‰ PDB the value assumed for mantle carbon carbonatites as also fall in this range⁹. The only exception were carbonados of Brazil with ¹³C = -27 to -30‰ PDB^{5,10} as well as some coloured diamonds from placers of the northern Yakutia¹¹. However, it has been established recently that among the diamonds from the placers of the Urals, Sayans, Ukraine and from other areas of the USSR there are monocystals with light ¹³C = -20 to -25‰ PDB and intermediate ¹³C = -10 to -20‰ PDB isotopic composition of carbon⁵. Kaminsky *et al.*¹² have even suggested that such diamonds are of non-kimberlitic origin. In this connection, the discovery of isotopically light diamonds in Lesotho kimberlites is very significant. From these descriptions of the diamonds and from Table 1, neither the habitat of the stones nor their colours are related to a particular isotopic composition. Among the isotopically light diamonds there are rounded dodecahedra and octahedra which are colourless or have a yellow or smoky colour. This isotopic composition of diamonds probably depends on their genetic peculiarities but further study on this is required.

New data on natural todorokites

TODOROKITE has been found as a product of terrestrial weathering, in sedimentary manganese ore, in deep-sea iron and manganese nodules and crusts. It is considered as an important source of Ni, Co, Zn, Cu, Mg in marine manganese nodules.¹⁻³

We show here that besides previously described todorokites with parameters $a_0 = 9.75$, $b_0 = 2.84$ and $c_0 = 0.6$ Å there are others, one with $a_0 = 14.6$ Å (The Pacific Ocean, Bakal) and one with $a_0 = 24.38$ Å (Bakal, Sterling Hill), b_0 and c_0 being unchanged. Morphologically the todorokites with different a_0 are very similar—their a_0 -values being multiples of 4.88.

According to Straczek *et al.*⁴, the approximate formula of todorokite might be $(\text{Na}, \text{Ca}, \text{K}, \text{Mn}^{2+})(\text{Mn}^{4+}, \text{Mn}^{2+}, \text{Mg})_6\text{O}_{12} \cdot 3\text{H}_2\text{O}$. The extent of variations of Mn^{4+} , Mn^{2+} , and Mn^{3+} are still unknown. The symmetry of the mineral is orthorhombic (or monoclinic, β about 90°), with $a_0 = 9.75$, $b_0 = 2.84$ and $c_0 = 9.59$ Å. In electron microscope preparations todorokite occurs in the form of thin lathes (001) frequently elongated along the b axis.

Burns and Burns^{1,5} assumed that the todorokite structure was similar to that of hollandite and psilomelane and had common features with the structure of rutile, this being shown by their ability to produce planar net trillings of elongated crystals. The intergrowths of todorokite form nets of hexagonal, triangular and rhombic cells. The electron micrographs of the treble intergrowths show three superimposed diffraction patterns orientated to each other with a relative rotation at an angle of 120° (Fig. 1). From selected area electron diffraction (SAD) todorokite has been shown to occur in the form of lathes with a basal face (001).

A study of SAD-patterns revealed that besides the todorokite having $a_0 = 9.75$, $b_0 = 2.84$ and $c_0 = 9.59$ Å found in many deposits, species with $a_0 = 14.6$ (Fig. 1c) and 24.38 Å (Fig. 1d), the b_0 and c_0 parameters being unchanged, occur in the natural environment. Under the microscope and on the electron micrographs these species look similar to todorokite with $a_0 = 9.74$ Å. The results, obtained from an analysis of individual lathes of todorokites with different values of the a_0 parameter carried out with an EM 100 C microscope and X-ray energy spectrometer (Kevex), indicate the similarity of their chemical composition. The X-ray powder patterns of these todorokite species display an insignificant difference between the parameters, which is reflected in slight variations of spacings for some reflections, hkl . The X-ray patterns failed to show weak reflections indicative of a true value of the a_0 parameter of todorokite. The strong reflection $hk0$ and 001 of structural varieties of todorokite largely correspond to the same lattice spacings.

It is easy to see that the values of a_0 characteristic for the members of the todorokite group (9.75, 14.6, 24.38 Å) are

divisible by 4.88 Å. The variations of this parameter are shown by the frequency of the reflections occurring along the axis a^* . For example on an electron micrograph showing the todorokite basal plane (001) with $a_0 = 9.75$ Å (Fig. 1b) there are three less-intense reflections along the a^* -direction between the strong reflections forming a pseudohexagonal net. The first strong reflection along the a^* axis has indices 400 ($d = 2.4$ Å). In the SAD pattern of the todorokite with $a_0 = 14.6$ Å (Fig. 1c) there are five weak reflections between the strong ones. In this case, the reflection at $d = 2.44$ Å along the a axis has indices 600. On the pattern of todorokite with $a_0 = 24.40$ Å (Fig. 1d) there are, between the strong reflections along the a axis, four weak reflections on each side, which, provided other reflections are absent, would determine a base-centred unit cell and the extinction law for the plane (001)*— $h+k=2n$, where n is an integer. However, on the diffraction pattern of the todorokite species with $a_0 = 24.38$ Å, midway between the strong reflections, there is the fifth, weak, reflection which violates the symmetry of the unit cell and shows it to be really primitive. In this case, the strong reflection at $d = 2.44$ Å occurring on the a^* axis has indices 10.0.0.

Under the microscope todorokite with the parameter $a_0 = 14.6$ Å is seen to occur in the nucleus of an iron-manganese nodule collected from the Pacific Ocean floor. Flaky todorokite from the Bakal deposit (USSR) seems to consist of aggregates of two todorokite species with the a parameters 14.6 and 24.4 Å. Todorokite with $a_0 = 25$ Å has been identified in a sample from Sterling Hill (USA) and a specimen from the Takhta-Karacha deposit in the Middle Asia.

Thus, todorokite species may be characterised by unit cells having different parameters a_0 which is divisible by 4.88 Å (the parameter along the a axis being determined by strong reflections located in accordance with the pseudohexagonal law, if there is a base-centred orthogonal unit cell). We assume that todorokites with other a_0 parameters, but still divisible by 4.88 Å, do also exist in nature.

The variations of the a parameter and formation of the todorokite superstructures will probably be attributed to certain difference in their composition and the environment of their crystallisation.

The data available show that todorokite is displaced by vernadite (δMnO_2). Even after a complete displacement of todorokite by vernadite, the former retains its fibrous or flaky appearance. Therefore, the products of partial or complete replacement of todorokite by vernadite can be erroneously taken for todorokite, without comprehensive electron microscopic examination. Partially vernadite-replaced todorokite as well as the pseudomorphs of vernadite after todorokite are common.

In view of the possibility of a new species of todorokite family being found in nature as well as in synthetic products, we recommend the following nomenclature: todorokite I with $a_0 = 4.88$ Å; todorokite II with $a_0 = 4.88$ Å $\times 2$; todorokite III with

Fig. 1 a, electron photomicrographs of the todorokite treble intergrowths. b, c, d, Electron diffraction pattern of monocystal of todorokite with parameter $a_0 = 9.75$ Å (b), and of treble intergrowths of todorokite with parameters $a_0 = 14.6$ Å (c) and 24.4 Å (d).

$\iota_0 = 4.88 \text{ \AA} \times 3$; todorokite IV with $a_0 = 4.88 \text{ \AA} \times 4$; todorokite V with $a_0 = 4.88 \text{ \AA} \times 5$. (Todorokites II, III and V have been already found in nature.)

Predictions made by other authors have a direct bearing on the discovery of todorokite polymorphs. They deal with pure crystalline manganese oxides and hydroxides (see refs 5, 6). According to Turner and Buseck⁷ mixtures of polymorphs found recently have also been known for other manganese oxides—hollandites and cryptomelanes.

Rates of Holocene folding in the coastal Zagros near Bandar Abbas, Iran

FOR the study of recent crustal processes, seismological and geodetic surveys need to be complemented by measurements of Earth movements over periods long enough for secular trends to emerge¹. The one such item available for the Zagros was obtained in 1952, when Lees and Falcon used archaeological remains to trace the growth over the past 1,700 yr of the Shaur anticline near the head of the Persian Gulf². Lees and Falcon also observed that recent marine terraces on the shores of the Gulf had been deformed by anticlinal growth². I report here

Fig. 1 Location of sections. Main fold axes (heavy lines) after Berberian¹⁷. Broken heavy line shows approximate position of Minab Fault. Arrows are normal to generalised strike of corresponding anticline and denote shortening vectors; bearing of resultant **R** (Table 2) based on vectors at sections 1 and 2, which are at right angles.

Fig. 2 Age/height plots for section 1 (●) and sections 2 and 3 (■) corrected for eustatic factor after Flint⁷; corresponding open symbols (○, □) corrected after Clark et al.⁸. Solid lines are least-squares fits for former, dashed lines for latter. Age error bars denote 1 s.d. No correction has been made for 'apparent age' at death of molluscs, which would shift all points to the left.

preliminary ¹⁴C dates on shells from fossil beach deposits associated with three fold structures on the eastern Zagros coast of Iran near Bandar Abbas, and derive Holocene deformation rates from them. The results, though not necessarily applicable to other parts of the folded belt, are compatible with estimates of the current rate of rotation of Arabia, to whose northeasterly drive the Zagros Range has been ascribed³.

The samples were collected for a survey of recent coastal movements⁴ which, in view of the uncertainty that surrounds global (eustatic) sea-level history, is confined to the relative displacement of isochronous shorelines⁵. For the present work, however, absolute values of vertical displacement are needed and hence allowance must be made for fluctuations in sea level. Data from other parts of the Gulf cannot be used for this as they may embody the tectonic effects we are trying to isolate. For this reason, and also to facilitate eventual comparison with data from the Makran⁶, the corrections adopted below are based on the empirical global curves favoured by Flint⁷, which indicate progressive if decelerating submergence during the Holocene, and on the model formulated by Clark et al.⁸, which for the latitudes at issue yields slow emergence over the past 7,500 yr.

The folds of the southern Zagros east of Bandar Abbas swing round parallel to the coast. The first section considered here, 2 km south of Tujak (1 on Fig. 1), consists of a succession of beaches cut into marls of the Mio-Pliocene Agha Jari Formation which were exposed by erosion of an anticline striking N 160° E. The beaches are capped by 0.5–1.5 m of fossiliferous sands whose lithology, form and faunal content reflect intertidal conditions⁹. Three of the beaches were sampled for dating. Each sample consisted of a single species of mollusc; thin-section analysis, X-ray diffraction and inspection under the scanning electron microscope were used to identify unaltered specimens.

The second set of dates refers to two anticlines west of Bandar Abbas which are also composed of late Tertiary rocks. Unrecrystallised shells were obtained from the summit of a beachrock on the southern flank of one of the anticlines, which strikes roughly N 60° E and consists of sands and marls of the Miocene Mishan Formation (3 on Fig. 1), and from an abandoned offshore bar and a beach terrace on the southern flank of the other, which strikes N 70° E and includes both Agha Jari and Mishan deposits (2 on Fig. 1). The results from sections 2 and 3 are treated together; additional dates should make it possible to establish differences between the histories of the two structures.

The ¹⁴C ages obtained for both coasts are listed in Table 1 and, after eustatic correction, plotted against height in Fig. 2. The presence of successive discrete beaches, notably at section 1,

suggests that movement was spasmodic, but average uplift rates can still be informative. Table 2 lists the values obtained both by assuming uniform uplift since the formation of the highest sea-level indicator and by calculating least-squares lines for the data. The maxima obtained are 7.4 mm yr⁻¹ for section 1 and 1.9 mm yr⁻¹ for sections 2 and 3. These figures lie between the minimum average of 1 mm yr⁻¹ that has been proposed for general uplift of the Zagros Mountains³ since the early Pliocene, and the rate of about 12 mm yr⁻¹ obtained for the Shaur anticline². A Holocene rate of 6 mm yr⁻¹ has been calculated for subsidence of the Musandam Peninsula at the mouth of the Gulf¹⁰; data from Qatar¹¹ give uplift rates of 1.1 and 0.3 mm yr⁻¹ according to which eustatic correction is adopted.

A preliminary assessment of the horizontal shortening represented by the observed uplift can be made using purely geometrical methods and assuming that the folds approximate

The values for ΔX for sections 2 and 3, which represent northward compression, are probably minima, as shortening is likely to be taken up in part by other anticlines inland and offshore. Folding due to eastward shortening at section 1 is confined to a narrow belt by the Minab Fault to the east¹², but evidence at the Chah Shirin Fault near Minab for 3.5 m of north-eastward thrusting over the past 7,000 yr (ref. 15) suggests that on this coast also the calculated shortening is a minimum. At all events the ΔX values give results (Table 2) which range between 16.6 and 31.9 mm yr⁻¹ and bear roughly NNE. Palaeomagnetic evidence from the Red Sea and the Gulf of Aden indicates separation between Africa and Arabia at a rate of about 20 mm yr⁻¹ during the past 5 Myr and a spreading axis in the western Gulf of Aden with a strike of N 110° E (ref. 16). The relationship between the two sets of results needs to be scrutinised.

Heights corrected for eustatic factor after Flint⁷ (a) and Clark *et al.*⁸ (b).

symmetrical curves of intrinsic sine form. Let L be the length of the fold surface between two troughs and ω the maximum slope of the limbs. During compression with horizontal displacement ΔX , the vertical displacement Δy of a point P on the fold at a distance s along the fold limb from one of the troughs can be approximated (C. D. Mann, personal communication) by the expression

$$\Delta y = \Delta X \times 2\pi/\omega \times (s/L)^2$$

where s/L is small and the folded zone is bounded at the base by a surface of discontinuity (décollement)^{3,12}. Known values for L , ω , s and Δy , and calculated values of ΔX , are given in Table 2. L , s and ω were derived from field measurements and air photographs for sections 1 and 3, and from geological cross-sections constructed from published maps¹³ by the Busk method¹⁴ for section 2. The many minor faults associated with all three structures have been disregarded.

Movement on the Chah Shirin Fault had apparently ceased by 1,250-yr BP¹⁵; the least-squares plots for section 1, like those for sections 2 and 3, suggest that uplift stopped 1,300–1,000 yr BP. Further age determinations and field mapping are required to establish whether this is an artefact of dating and to refine the uplift plots so that the underlying mechanisms can be explored.

I thank M. G. Ghorashi, C. D. Mann, D. J. Shearman, J. D. Taylor and B. M. Walker for help, the Central Research Fund of London University, the Centre Scientifique de Monaco, the NERC and the Royal Society for radiocarbon dates and isotopic data, the Geological Survey of Iran for field support, and R. H. Sibson for helpful comments.

Ordovician fish spines from Girvan, Scotland

THE Upper Ordovician Lady Burn Starfish Beds¹ of the Drummuck Group² in the Craighead inlier have long been known for their well-preserved, diverse and abundant invertebrate faunas^{3,4}. The trilobite⁵ and brachiopod (D.A.T.H., unpublished data) faunas indicate a late Rawtheyan (Ashgill) age for these predominantly green medium grained sandstone beds. Moreover, a study of the brachiopod associations and sediments of these beds together with the rocks above and below suggests that, although the Starfish Beds contain essentially 'shelf' faunas, final deposition was in a relatively deep-water, proximal slope environment⁶. I present here geochemical and morphological evidence of fish spines from these deep-water, siliciclastic marine rocks of Ordovician age at Girvan, south-west Scotland.

The occurrence of a pair of fish spines in the oldest and most fossiliferous of these marine strata at the South Threave locality (GR NS 250 038) is an unusually early appearance of this type of vertebrate material in the fossil record. The spines (Fig. 1) are subparallel and lie on a very fossiliferous bedding plane, which is crowded by disarticulated and randomly orientated valves of the Ashgill brachiopod *Eochonetes advena* Reed, 1917. The better preserved spine is 13 cm long, broken proximally and slightly curved. It is composed of predominantly black, apparently fibrous and lustrous material. Although now somewhat flattened, the spine seems to have been crudely rectangular in cross-section and has a hollow central canal.

Fig. 1 Ordovician fish spines embedded in fossiliferous bedding plane.

Fig. 2 SEM photomicrographs of spine fragment showing relatively simple bone histology. a, Oblique transverse view; b, oblique longitudinal view.

Electron microprobe analysis (D. C. Johnston, personal communication) indicates the composition of the material to be close to that of francolite, a carbonate-hydroxyfluorapatite commonly found as vertebrate bone.

Scanning electron microscope (SEM) photomicrographs (Fig. 2) of fragments of the material show the bone histology to be relatively simple; the oblique transverse (Fig. 2a) and longitudinal (Fig. 2b) views demonstrate the microstructure to be fairly massive, but with well developed growth rings about 20 μm apart. Interpretation of the cellular structure is difficult but in transverse section numerous minute pores perforate the substance; these presumably link with the central canal.

The morphological and geochemical evidence thus clearly demonstrate that these fossils are composed of vertebrate bone material and are best interpreted as fish spines; unfortunately no fish scales have been recovered.

Fish material is rare in rocks of pre-Silurian age, and when such remains are found they tend to be fragmentary⁷. The Ordovician occurrences, for example the Lower Ordovician Valhallfonna Formation of Spitzbergen⁸ and the Middle Ordovician Harding Formation of Colorado⁹, are usually represented by disarticulated heterostracan scales and cartilage. Similarly the earlier Cambrian record¹⁰ is marked by heterostracan plate fragments and tubercles. Although the similarly fragmentary nature of the later Girvan material does not allow an unequivocal determination, it cannot at present be related to any known fossil of Ordovician age. Most probably the spines are those of an acanthodian (spiny shark); note that the acanthodians are particularly characterised by paired fin spines¹¹. The close association of the spines suggests that the fish, or at least that part of the fish bearing the spines, had undergone negligible transportation since falling on to the substrate.

Recent studies of Palaeozoic fish¹² record the earliest appearance of acanthodians as Upper Silurian; in rocks of this age these fish are again represented by disarticulated spines and scales. The evidence from the Drummuck material, which strongly suggests that the pair of spines was part of a large specimen of acanthodian, significantly extends the stratigraphical range of these fish back into the Upper Ordovician.

The small amounts of the present material and lack of any comparable pre-Silurian occurrences do not allow much discussion on the origins of these spiny fish. It is, however, probable that by the later Ordovician the first marine vertebrates included at least both acanthodian and heterostracan fish.

I thank R. E. H. Reid for his encouragement and Professors D. L. Dineley and A. D. Wright for their comments. R. Reed and his staff assisted with SEM work and the plates are by Seán Watters.

Growth rings in dinosaur teeth

ANNUAL growth rings are often found in the skeletal tissues of Recent and fossil ectothermic vertebrates^{1,2}. These rings are usually attributed to the inability of ectotherms to maintain high levels of activity, feeding and growth during adverse times, such as dry seasons in tropical areas and cold seasons at higher, more temperate latitudes¹. In endothermic vertebrates, however, the efficient production of endogenous heat results in a relatively constant body temperature, and high activity and feeding levels are more easily sustained. Consequently, the growth of skeletal tissues in these animals is less sensitive to seasonal variations than in ectotherms, and annulations are rare except in species living under severe seasonal regimes^{3,4}. Many workers have proposed that dinosaurs were endothermic, as are all living mammals and birds, rather than ectothermic, as are all living reptiles^{3,5–10}. In accordance with this hypothesis, pronounced seasonal growth rings have not been observed in the calcified tissues of dinosaurs^{5,6}. However, here I report the discovery of such rings in the teeth of diverse Late Cretaceous dinosaurs.

Underwater screening for small vertebrate fossils has led to the recovery of hundreds of dinosaur teeth from the non-marine Milk River (early Campanian), Oldman (middle Campanian) and Edmonton (Maestrichtian) formations of Alberta, Canada. The teeth include those of Saurischia (Tyrannosauridae (Fig. 1) and Coeluridae) and Ornithischia (Hadrosauridae (Fig. 2a), Ceratopsidae (Fig. 2b) and Ankylosauridae). Ground and polished sections, as well as acetate peels of etched surfaces, have revealed conspicuous rings in the dentine in all dinosaur groups examined. Two main types of rings occur (Fig. 1): first, contour lines of Owen, which in Recent species mark minor nutritional and metabolic variations during the deposition of

Fig. 1 *a*, Cross-section of a tyrannosaurid tooth, Milk River Formation, Alberta; c.l.o., contour lines of Owen; 1–8, annual layers in order of deposition ($\times 7.2$). *b*, Cross-section of a tyrannosaurid tooth, Oldman Formation, Alberta; n.b., narrow band; b.b., broad band; a.l., annual layer; 1–8, annual layers in order of deposition; p.c., pulp cavity ($\times 4.2$).

dentine and are accentuated according to the degree of disturbance experienced¹¹; and second, larger rings matching those of various Recent species^{4,12}, in which a narrow hypercalcified band (winter's growth) and a broad hypocalcified band (summer's growth), produced by seasonal variation in growth rate of the organic stroma of dentine, constitute an annual layer¹². Histologically, then, the structure of the dentine of dinosaurs indicates a periodicity in growth; the significance of this for the controversy concerning dinosaurian physiology is apparent when the clarity and pattern of the rings are compared to those in Recent and fossil organisms of known thermal physiology.

The only living terrestrial endotherms with annual layers of dentine as evident as those in Alaskan dinosaurs are mammals of Arctic or temperate regions^{4,12,13} subject to marked seasonal contrasts. Of tropical and subtropical mammals, only certain Australian marsupials^{4,12} and various African ungulates^{14–17} have been extensively investigated and no distinct annual layers in the dentine or bone have been reported, although layering in the cementum of some of the ungulates may correlate with wet and dry seasons. Consequently, if dinosaurs were endothermic and comparable to mammals in their thermal physiology, seasonal contrasts in Alberta during the Late Cretaceous must have been comparable to those of temperate and Arctic North America and Eurasia today to have produced conspicuous annual layers in the dentine.

However, severe seasonal contrasts do not seem to have characterised Alberta during the Late Cretaceous: palaeobotanical¹⁸ and palaeontological studies¹⁹ indicate a warm, subtropical climate without extreme daily or seasonal temperature change throughout the western interior of North America. If dinosaurs were endothermic in these conditions, how are the pronounced growth rings in their dentine to be explained? The

Fig. 2 *a*, Cross-section of a hadrosaurid tooth, Oldman Formation, Alberta, Canada ($\times 3.15$). *b*, Cross-section of a ceratopsid tooth, Oldman Formation, Alberta, Canada ($\times 5.04$).

origin of the rings is clearer, however, if dinosaurs were ectothermic, and thus presumably sensitive to relatively mild seasonal contrasts of temperature.

Fossil crocodile teeth (Fig. 3a) from the same localities as the dinosaur teeth have well developed rings, particularly similar to those of tyrannosaurids. No appreciable difference in pattern or clarity of annual layers or contour lines of Owen was found between the dentine of crocodiles (which are known ectotherms) and that of dinosaurs, suggesting that these organisms had a similar physiological tolerance to environmental fluctuations and hence a similar thermal physiology. Crocodile teeth from different geological settings, from Palaeocene and Eocene beds in Saskatchewan and Wyoming, also have growth rings like those of the Upper Cretaceous crocodiles and dinosaurs, thereby eliminating preservational bias.

Fig. 3 a, Cross-section of a crocodile tooth (probably *Leidyosuchus* sp.), Oldman Formation, Alberta, Canada ($\times 3.6$). b, Cross-section of the root of an incisor of *Entelodon* sp., Oligocene, Cypress Hills Formation, Saskatchewan, Canada ($\times 3.0$).

Undoubted endotherms of large body size had not evolved by the Late Cretaceous and thus cannot be compared with dinosaurs. In teeth of small Late Cretaceous endotherms (mammals such as *Protungulatum*, *Didelphodon* and *Gypsonictops*) dentinal rings were not observed. Teeth from Tertiary mammals (representing four orders—Condylarthra, Amblypoda, Perisodactyla and Artiodactyla—and from formations interpreted as representing subtropical to warm temperature regimes) did show contour lines of Owen (Fig. 3b); however, apparent annual banding was rare and poorly developed.

As annual layers in most dinosaur and crocodile teeth are appreciably more conspicuous than in the Tertiary mammalian specimens, these reptiles were evidently affected to a greater degree by environmental factors influencing their growth rates. Furthermore, in the dinosaur and crocodile teeth, but not in the Tertiary mammal teeth, contour lines of Owen were often accentuated and tightly packed near and within the narrow bands of the annual layers: perhaps the crocodiles and dinosaurs were more sensitive to minor metabolic and nutritional stresses, particularly near and during adverse seasons, than were the Tertiary mammals examined.

In summary, the growth rings in the dentine of dinosaurs are more like those of contemporary crocodiles (known ectotherms) than those of fossil or Recent mammals from comparable climatic regimes. Evidently, growth and calcification of dentine in Late Cretaceous dinosaurs and crocodiles were affected similarly by both short-term and seasonal environmental variations, suggesting that these animals had similar thermal physiologies. If dinosaurs were ectothermic, their annual layers (as well as those of crocodiles and other organisms such as *Champsosaurus*, *Lepisosteus* and *Taxodioxylon* (unpublished data from the Late Cretaceous of Alberta)) seem best explained by Dodson's hypothesis²⁰ of seasonally distributed rainfall; by analogy, Recent crocodiles in Ngamiland exhibit annual layers in the periosteal bone apparently due to temperature fluctuations associated with wet and dry seasons characteristic of that tropical area¹.

R. C. Fox provided funds for this study (National Research Council of Canada grant A-3408) and I thank him for reading the manuscript.

Analogous motion illusion in man and fly

SINCE Wertheimer's classic paper¹, research in motion perception has been concerned with the study of visual illusions such as ϕ -motion. Various phenomena of this type are easy to elicit by successive changes of the light flux in spatially distinct photoreceptors, and easy to explain by the specific properties of the motion detectors, although there are reports to the contrary². The present account deals with a less easily comprehensible illusion which is elicited by simultaneous changes of the light flux in differently illuminated receptors³⁻⁵. The phenomenon has previously been ascribed to the prolonged latency of the 'light-on' responses at lower levels of illumination which converts simultaneous stimuli into successive signals⁶, but this does not explain the illusion satisfactorily³. MacKay and co-workers were the first to attribute the apparent motion to the adaptive properties of the input channels of the motion detectors⁴. We show that the illusion can be induced in the fruitfly, *Drosophila melanogaster*, as well as in man. The course control response to motion provides a quantitative assay of the illusion in the fly. The results suggest that the illusion originates in the distortion of the visual signals before motion detection.

To elicit the illusion in humans we illuminated transparent optical wedge filters of linearly graded density with a variable light source. The observer of the circular array in Fig. 1a usually perceives a spurious 'propeller' behind the pattern which rotates a few degrees towards the less transparent side of the wedge filters during light increase, and in the reverse direction during light decrease. The predominant sensation is oscillatory rotation at modulation frequencies of 0.3–2 Hz, continuous rotation towards the less transparent side of the filters at 5–12 Hz and ambiguity at 2–5 Hz.

Motion around a fly evokes vigorous turning in the direction of the horizontal displacement. The response counteracts involuntary deviations from a straight course in a stationary environment. Turning is induced by a regular network of elementary motion detectors. The network accepts stimuli from all parts of the visual field, and acts on the difference between the

propulsive forces on either side. With the fly held in a stationary position the course control responses of wings⁷ or legs⁸ can be measured quantitatively. Figure 1*b* illustrates the paradigm used to assay apparent motion during fixed flight. The results in Fig. 2 reveal the existence of a motion illusion in *Drosophila* which is strikingly analogous to the corresponding illusion in man. The illusions coincide with respect to the phase and direction of the oscillatory component at low modulation frequencies, and with respect to the direction of the continuous component at high modulation frequencies of the illumination. Maximum intensity and spectral composition of the light source do not seem to be critical in the range 0.003–300 cd m^{-2} .

In the fly the illusion originates within the network of bidirectional motion detectors, each comprising motion-specific interactions between neighbouring input units of the visual system⁸. The steady-state responses of the detectors are adequately described by the correlation model in Fig. 3, where the interaction is achieved by multiplication of two input signals. The model is representative of all 'simple' motion detectors which do not require more than the theoretical minimum of two input units in second-order nonlinear interaction⁹. Models of this type are equivalent in their steady-state responses, and seem to be sufficient to describe the properties of entirely different motion detection systems, such as the direction-selective retinal ganglion cells in vertebrates^{10,11}. The models respond to successive stimulation of their input units and cannot discriminate true motion from the corresponding φ -motion. Figure 3 shows the simultaneous sinusoidal stimulation of the receptors in the present paradigms. The visual input is characterised by the transmission-dependent mean intensities $\bar{I}_1 > \bar{I}_2$, and by the transmission-independent relative amplitude, or modulation, $\Delta I/\bar{I} = \Delta I_1/\bar{I}_1 = \Delta I_2/\bar{I}_2$. In the linear range of signal processing at the receptor level (N) the gain factor of the response, R , of the model is $\bar{I}_1 \bar{I}_2 (\Delta I_2/\bar{I}_2 - \Delta I_1/\bar{I}_1) = 0$. This is easy to show by application of the operations specified in Fig. 3. The absence of responses at the level of motion detection excludes the generation of the expected responses at subsequent levels. Nonlinear processing of the simultaneous signals before motion detection becomes necessary to elicit non-zero responses from the detector model.

Fig. 1 *a*, Circular array of wedge filters used to elicit, stroboscopically, the illusion of oscillatory (0.3–2 Hz) or continuous (5–12 Hz) rotation in the human observer. The best results were obtained with a transparency of the pattern (absorbance 0–2), illuminated from behind by a sinusoidally modulated light source of almost arbitrary colour and intensity. It may be difficult to see the illusion when the figure is directly exposed to flickering light. *b*, Cylindrical array of wedge filters surrounding the fruitfly *Drosophila* during fixed flight on a torque meter which is used to record the course control response. The stationary pattern was illuminated from outside by a programme-controlled central light source in the lower compartment. The panorama was inverted between experiments and was presented in arbitrary angular positions to minimise lateral disparities of stimulus and response.

Fig. 2 *a*, Oscillatory motion illusion response of the fruitfly during fixed flight in the experimental set-up of Fig. 1*b*. The shaded area shows the actual light programme ($I_{\max} = 0.003 \text{ cd m}^{-2}$). The upper diagram shows the torque about the vertical axis produced in a single experiment. Increasing torque indicates the increasing tendency to turn towards the less transparent side of the filters, and vice versa. The dots in the lower diagrams refer to the responses of 12 flies, or the averages of 257 subsequent cycles of stimulation. The solid curves represent the motion illusion response of the model in Fig. 3. The oscillatory motion illusion of the fly is predictable and resembles the illusion induced in the human observer. *b*, Continuous motion illusion response of the stationary walking fruitfly as a function of the frequency of sinusoidal light modulation in the panorama of Fig. 1*b*. The tendency to turn was measured in revolutions per metre pathlength. The means and s.e.m. refer to the time averages of the responses of 11 flies which covered a total pathlength of 2,200 m in 250 h.

Surprisingly, the characteristics describing the apparent saturation of photoreceptors in quasi-static conditions, $X(t) \sim I(t)/(I(t) + I_0)$; $I_0 = \text{constant}$ (refs 12, 13), are apparently sufficient to elicit the expected oscillatory responses. To calculate R , the receptor output, $X(t)$, may be developed into a power series about $\bar{I}$. The first-order term accounts for a positive gain factor $I_0(\bar{I}_1 - \bar{I}_2)\Delta I/\bar{I} > 0$ and describes the illusion qualitatively. The results of a quantitative simulation are shown in the lower sections of Fig. 2*a*. The solid curves approximate the oscillatory responses of the fly with respect to (1) the light-on effect, (2) the light-off effect, (3) the phase lead on the periodic stimulus¹⁴, and (4) the decrease of the response with

Fig. 3 Motion detector model used to describe the perception of both true and apparent motion in man and fly. The figure shows the attenuation of a sinusoidally modulated light source by a wedge filter. The simultaneous signals, I_1 and I_2 , are nonlinearly transformed (N) into the input signals, X_1 and X_2 , of a motion detector of the Reichardt-Hassenstein type⁹. The model consists of linear elements (L) for the retardation, and nonlinear elements (M) for the multiplication, of the input signals. It produces responses R of opposite sign if the direction of motion is reversed. Partition of the bi-directional motion detector into uni-directional antagonists imposes no constraints on the present results. The motion illusion obtained with the model is due to the nonlinear properties of N . The responses disappear if N becomes linear.

increasing background illumination. The matched parameters $I_0 = 0.04 I_{\max}$ of the receptor characteristics (N), and the matched time constant $T = 10$ s of the low pass filters (L), are also appropriate for the simulation of the response to true motion.

The simulated illusion decreases with progressing linearisation of the receptor characteristics at higher frequencies of stimulation. Concurrently, dynamic receptor nonlinearities become important, in particular, the prolonged latency of the light-on signal of the receptor output at lower levels of illumination^{15,16}. Latency differences between the light-on signals in the present experiments lead to successive stimulation of the input units of the motion detectors in the expected direction, towards the less transparent side of the wedge filters. The oscillatory motion illusion cannot be explained by prolonged latency. Qualitatively, there is no resemblance between the rebound of the transient light-on response $R > 0$ of the model and the marked light-off effect shown in Fig. 2a. Quantitatively, latency differences of 0–25 ms in man⁶, or 0–5 ms in the fly¹⁷, seem to be too small to contribute significantly to the oscillatory motion illusion³. However, accumulation and fusion of latency-induced transients $R > 0$ seem to account for the continuous motion illusion at higher frequencies of stimulation in Fig. 2b. The negative responses at medium frequencies are possibly due to the inversion of the brightness gradient at the edges between neighbouring wedge filters.

The results obtained permit the classification of various types of motion illusion according to their origin within the visual system. Unlike ϕ -motion² the present illusion requires nonlinear signal processing before motion detection, and is adequately, though not necessarily⁴, explained by the intensity dependence of gain and latency at the receptor level.

Activity of an identified wind interneurone in a flying locust

LOCUST flight has been intensively studied by behavioural physiologists. The basic flight rhythm seems to be generated within the thoracic ganglia¹, although its timing is modified from wing beat to wing beat by phasic input from the wing sense organs². In this way, the basic motor score is possibly tuned to operate at the resonant, most energetically efficient frequency of the individual insect, and adjusted to accommodate changes in wing movements caused by variations of the external air current. Sensory influences on the flight motor neurones do not only originate at the wings. Weis-Fogh has demonstrated that stimulation of the wind-sensitive head hairs causes tonic excitation of these motor neurones³. Here, we have recorded in the locust during flight, the activity of two of the interneurones that convey wind information from the head hair afferents to the thoracic ganglia. These interneurones, the tritocerebral commissural giants (TCG)^{4,5}, receive their afferent wind hair input in the brain and make excitatory connections with flight motor neurones in the thoracic ganglia⁶. We show that these cells are rhythmically active during flight, synchronous with the wing beat, as a result of periodic stimulation of the head hairs. It is therefore possible that the wind-hair sensory system has a phasic influence on the flight motor as well as the already clearly established tonic influence.

We were able to record the activity of the TCG neurones during tethered flight because they take a curious path through the tritocerebral commissure, a nerve of small diameter (60 μ m) which loops under the gut and links the tritocerebral hemispheres of the brain (Fig. 1). With an axon diameter of 20 μ m, these interneurones are much larger than any of their neighbours in the commissure. This situation was exploited to make long-term recordings of the TCG at the commissure, using a chronically implanted hook electrode.

We used adult male *Locusta migratoria* from laboratory culture, selecting animals that demonstrated a strong willingness to fly. Insulated steel wires (diameter 30 μ m) were used to record from the interneurone and hind wing depressor muscle 129 in the thorax. Animals were supported at the sternum near

Fig. 1 Schematic view of the CNS in the head and thorax of the locust to show the structure of one of the paired TCG wind interneurons. The TCG is seen to pass through the tritocerebral commissure (tc) at which point it can be recorded with a hook electrode (Rec). The dotted line indicates the position at which the connectives were cut (see text). SOG, suboesophageal ganglion; ThG, thoracic ganglia. Scale bar, 0.5 mm.

the mouth of a wind tunnel producing a laminar air stream of 3.5 m s^{-1} .

Figure 2a shows the low level of spikes in the TCG interneurone in a resting animal exposed to a laminar air stream. In contrast, during flight the neurone displayed a much higher level of spiking activity which was rhythmical (Fig. 2b) and synchronised with the firing of a wing depressor muscle in the thorax (Fig. 2c). This effect persisted in animals flying in the dark, thus excluding the possibility that it arises from visual input produced by the movements of the wings.

The rhythmicity in the TCG neurone during flight may occur simply because the insect can sense phasic changes in turbulence around the head created by its own wing or head movements. Alternatively, the cell may receive rhythmical input from the flight motor or sense organs in the thorax, neck or abdomen. As the TCG has been observed to carry only descending information, such input would first have to reach the brain through ascending interneurons.

To investigate these two possibilities, we recorded the activity of the cell in an animal in which we had cut both circumoesophageal connectives behind the tritocerebral commissure (dotted line, Fig. 1). In these conditions of complete cessation of excitatory input from the head hairs to the flight motor neurones

in the thorax, flight was difficult to initiate and the wing beats were irregular. However, in a few cases continuous flight lasting up to 5 min could be induced. All lesions were verified after the experiment.

Figure 3 shows the results for an animal flying straight ahead. The activity of the cell was much diminished as a result of the lesion (Fig. 3a) but the infrequent spikes that occurred were synchronised with the firing of a wing depressor muscle in the thorax (Fig. 3b, c). Removing the antennae had no effect on this synchronisation.

Fig. 2 Activity of the TCG interneurone (top trace) and wing depressor muscle 129 right (bottom trace) in a locust suspended in a laminar air stream. *a*, The weak response of the TCG in a resting animal. *b*, During straight flight the neurone shows rhythmical activity. Timescale, 50 ms. *c*, Histogram showing time of firing of the TCG in relation to the activity of the muscle. Abscissa: time of occurrence of interneurone spike relative to muscle spike; ordinate: number of interneurone spikes. The histogram is a record of 3,695 TCG spikes sampled during 3,500 successive wing beats.

Firing of the TCG and muscle are well synchronised.

This experiment demonstrated clearly that the TCG receives rhythmical input from the wind-sensitive hairs on the head. In addition, the lower level of firing of the TCG in this preparation, compared with that in the intact animal, showed that ascending information is also a significant input to the cell. However, other experiments in which interneurone recordings were made from animals with their heads completely waxed over (but connectives intact) showed that this ascending input contributes none of the rhythmicity during flight. We therefore conclude that the flying locust is sensitive to the phasic air currents caused by the rhythmical flight movements of its own body.

Intracellular recording has revealed that this interneurone makes functionally direct excitatory connections with flight motor neurones in the thoracic ganglia⁶. Therefore these motor neurones receive a phasic excitatory input, through the TCG, from the wind-sensitive hairs during flight. It remains to be seen, however, whether the phasic information transmitted by the TCG (and presumably by other wind-sensitive interneurons) is a behaviourally significant fast-feedback loop for the flight

Fig. 3 Results obtained during straight flight in an animal in which both circumoesophageal connectives had been cut posterior to the tritocerebral commissure. *a*, Recordings of the interneurone (top trace) and the wing depressor muscle 129 right (bottom trace). Timescale, 200 ms. *b*, Expanded time axis showing interneurone spike in time with the contraction of the muscle. Timescale, 20 ms. *c*, Histogram showing time of firing of the interneurone in relation to the activity of the muscle, axes as for Fig. 2*c*. The data are a record of 48 TCG spikes sampled during 772 successive wing beats. Firing of the cell is fairly well synchronised with the contraction of the wing depressor muscle.

motor. Certainly, descending light-sensitive interneurons, when stimulated with a stroboscopic light, can entrain the flight frequency⁷. Perhaps some visual interneurons, able to detect the up-and-down movements of the wings, and wind-sensitive interneurons, work with the sensory inputs from the wings to set the optimum flight frequency for the insect. Alternatively, the phasic excitation that arises at the wind hairs, when conducted down the cord by many interneurons working in parallel, may arrive at the flight motor neurones as an integrated tonic excitation, and so function simply as a positive feedback mechanism to maintain flight. Further investigations using this preparation present exciting possibilities for a more detailed analysis of the neural basis of flight.

We thank Professors F. Huber and W. Nachtigall and Dr J. Altman for reading the manuscript. Drs W. Zarnack and H. K. Pfau discussed the results with us. The work was done using apparatus provided by a grant from the Stiftung Volkswagenwerk to Professor Nachtigall. J.B. is in receipt of a Max Planck Stipendium.

The segmentation of axons from the segmental nerve roots to the chick wing

THE chick wing is innervated by adjacent spinal roots which meet at the brachial plexus and then redistribute their axons to the peripheral nerves. Both the anatomical arrangement of nerves within the wing and the innervation territories supplied by each root are constant among animals of the same strain¹⁻³. We describe here the pathways taken by the axons from each of the main roots to their particular territories in the normal wing, and also in wings which have dorso-ventral and antero-posterior axes reversed relative to the host axes. Our observations suggest that the characteristic innervation territories of the segmental roots may arise from two basic rules: that axons travel in parallel over long distances without crossing, and that the branching pattern of nerves within the limb is determined by the local environment^{3,4}.

The motor and sensory innervation territories of the three segmental roots were mapped electrophysiologically *in ovo* at 17 d of incubation. Sensory innervation maps were constructed by mechanically or electrically stimulating localised regions of skin while recording from each nerve root in turn (Fig. 1). The motor innervation was mapped by stimulating each root in turn

Fig. 1 Responses, recorded from the peripheral cut end of n16 using suction electrodes, to electrical stimulation of the skin in the normal (to the left) and rotated (to the right) wings of 578. Positions of the bipolar stimulating electrode (0.5-ms pulse) are shown at the top of each column. The top trace in each pair shows the averaged response to 16 consecutive stimuli, the bottom trace the response to a single pulse. Calibration bar, 10 ms.

Fig. 2 Normal wing, n14 filled. Camera lucida drawings of transverse sections at four levels, all viewed from the elbow. Filled axons are shown in black; they occupy the anterior sectors of the radial and medio-ulnar nerves. Trunk axes shown, A, anterior; D, dorsal; calibration bar, 1 mm. *a*, Biceps nerve contains axons from n14 (arrowed). *b*, Triceps nerve (arrowed) has no filled axons, but n14 axons are clearly visible in the biceps muscle (arrowed). *c*, Filled axons leave the radial nerve at the patagial nerve. A photograph of this is shown in Fig. 4*a*. *d*, Patagial nerve with filled axons going to the web of the wing (arrowed). Biceps muscle cross-hatched, triceps muscle hatched. LAT DORS, latissimus dorsi muscle; EMR, extensor metacarpalis radialis; H, humerus; r, radial nerve; tri, triceps nerve; pc, posterior cutaneous nerve; m, median nerve; u, ulnar nerve; pat, patagial nerve.

while observing electrical events accompanying muscle contraction. In all animals of our strain (White Leghorns), the 14th segmental root (n14) innervates the proximal anterior region including the biceps muscle, and the 16th segmental root (n16) supplies the posterior and distal regions including triceps. The territory of n15 lies in between and overlaps both.

In our experimental animals the wing buds were rotated 180° at stage 19, a significant time before the axons invade the bud. These limbs develop autonomously^{3,6} with dorso-ventral and antero-posterior axes reversed with respect to the host. For simplicity we will refer to the axes of trunk and wing separately; thus, in control animals these axes are the same and in operated animals the wing axes are opposite to those of the host trunk. When we map the sensory and motor innervation pattern of these animals we find that n14 now goes to the posterior and

distal parts of the wing (including triceps and the hand), whereas n16 innervates the anterior region of the grafted wing (including biceps and the alar web). The pattern of innervation of the rotated limbs is therefore (within the limits of variation found in control animals) the converse of that in the normal wing (Fig. 1).

Dissection of animals after recording shows that the spinal roots meet to form a seemingly normal plexus in the trunk which

Fig. 3 Rotated wing, n14 filled. Camera lucida drawings of transverse section at four levels, all viewed from the elbow. Trunk axes are as shown, wing axes are the reverse, that is, anterior to the left and dorsal downwards. Filled axons are shown in black, they occupy the posterior sector of nerves in the graft. *a*, Triceps and cutaneous nerves with filled axons (arrowed). *b*, Triceps muscle contains filled axons (arrowed), biceps does not. Filled axons are also present in median and ulnar nerves (arrowed). *c*, Fascicle of patagial nerve begins to separate from radial nerve. *d*, Unfilled axons leave the radial nerve to form patagial nerve (arrowed). A photograph of this is shown in Fig. 4*c*. Abbreviations as for Fig. 2.

produces the normal main dorsal and ventral branches to the wing. On entering the rotated graft the dorsal branch apparently behaves as if it were the ventral branch forming the medio-ulnar nerve. The ventral branch behaves as if it were the dorsal branch forming the radial nerve. Thus, the anatomical arrangement of nerves within the graft is very similar to that found in the normal wing.

Fig. 4 Photomicrographs of transverse sections of radial nerve including the branch point of the patagiales nerve. The arrows at the bottom indicate trunk (host) axes for all photographs; D, dorsal; A, anterior. The sector surrounded by the dotted line forms the patagiales nerve. The arrows indicate filled axons. Calibration bar, 100 μ m. *a*, Radial nerve from section shown in Fig. 2c, n14 filled. *b*, Radial nerve from section taken from a similar level to Fig. 4a, in which n16 had been filled. *c*, Radial nerve from section shown in Fig. 3d. There are no filled fibres in the fascicle giving rise to the patagiales nerve although n14 was filled.

The anatomy and physiology of the rotated wings suggest that although the pattern of nerves is determined by the environment, the arrangement of axons within the nerves is non-selective. To test this directly we have traced the connections anatomically by filling the axons of each root in turn with cobalt chloride, which can subsequently be visualised after treatment with H_2S and silver intensification⁷⁻⁹. When we fill n14 in the normal wing, we find that its axons maintain their anterior position through the plexus and into the main dorsal and ventral nerves, whereas axons from n16 maintain a posterior position, and axons from n15 lie in the region between the two and overlap both. The distribution of axons within the nerves as they enter the wing is therefore related to their spinal root origin. We further find that the axons continue to run in parallel, maintaining their positions over long distances, certainly to below the elbow, so that the cross-sections of each nerve consist of sectors which have relatively homologous axonal origins (Fig. 2). When a branch leaves the main nerve from its anterior aspect it contains axons which have been running in the anterior sector (Fig. 2c, 4a). When a branch leaves the main nerve posteriorly it contains axons from the posterior sector (Fig. 4b). Thus, n14 axons enter branches to the alar web and the biceps, whereas n16 enters posterior branches such as the triceps and ulnar nerves.

In the rotated wings the axons of n16 enter the brachial plexus in the trunk in their normal posterior position with those of n14 in their normal anterior position. This arrangement is maintained through the plexus and into the graft (Fig. 3). Thus, the axons of n14 come to occupy posterior sectors of the wing dorsal and ventral nerves, and are then channelled into wing posterior branches, for example, triceps and ulnar nerves (Figs 3, 4c). Conversely, axons from n16 from their posterior sectors in the trunk nerves come to occupy anterior sectors of the wing nerves and travel down anterior branches to the alar web and biceps.

There is no accepted theory to explain how each segmental root comes to innervate its particular limb territory. Recently, ideas have polarised to two extremes: target specificity where axons actively seek out their 'appropriate' targets, or initial random outgrowth with 'inappropriate' axons being subsequently eliminated by cell death¹⁰⁻¹⁴. Our results suggest that the pattern of innervation results from the way axons travel together in parallel over relatively long distances and the manner in which the segmental roots combine together in the plexus. The fate of individual axons (once they have taken up a certain position in the plexus) is determined by the peripheral branching pattern, and this is clearly controlled by the environment rather than by the nervous system. We do not have any information on the spinal cord anatomy and the next stage of our investigation is to observe the motor neurone pools supplying such rotated grafts.

Single glutamate-activated channels in locust muscle

EVIDENCE indicates that glutamate-activated membrane channels (glutamate channels) are responsible for the post-synaptic potential at insect¹ and crustacean² excitatory neuromuscular junctions. They may also be involved in the regulation of pre- and postsynaptic activity in the central nervous system of vertebrates^{3,4}. Analysis of the current noise produced by application of glutamate to excitatory synapses on locust muscle suggested that glutamate channels have a conductance of about 125 pS and a mean open time of about 2 ms (refs 5, 6). Direct measurements of the currents passing through individual acetylcholine-activated channels (ACh channels) in

Fig. 1 The currents through single glutamate-activated channels in the metathoracic extensor tibiae muscle of a 6-d denervated locust (*Locusta migratoria*). The muscle cell was voltage clamped with standard techniques, and the membrane potential held at the values shown next to each trace. A patch electrode filled with physiological saline containing 100 μ M L-glutamate was pressed on to the surface of the cell, and measured the currents passing through the muscle membrane under the patch. The electrode had a 2- μ m fire-polished tip which had a free-solution resistance of about 2 M Ω . When pressed on to the cell, the resistance increased to more than 10 M Ω , electrically isolating the membrane patch with a voltage divider ratio (leak to series resistance) of more than 5. The downward events are currents passing from the electrode into the cell. The background noise is the Johnson noise expected for the combination of the series and leak resistances. The patch electrode was placed within a cell diameter of the intracellular voltage electrode. Currents measured from the patch electrode were amplified and stored on an analogue FM tape recorder. The illustrations were made by play-back of the data through an active 4-stage filter ($f_c = 450$ Hz) with Bessel characteristics. All three records were from the same patch. The temperature was 21 $^{\circ}$ C. Standard locust physiological saline was used for all experiments. The cell had been previously treated for 15 min with 1 μ M Con A in saline, then washed with normal saline for more than 30 min. No single channel responses could be measured when the glutamate was omitted from the patch electrode.

Fig. 2 Current-voltage characteristics of single glutamate channels. Patch recordings at various different membrane potentials were sampled with a PDP 11/34 computer, and channel amplitudes measured as the difference between the average value of the current 2 ms before and after individual current steps. *a*, Histograms of measured step sizes at two membrane potentials, -60 and -110 mV. Channel amplitudes measured by hand from strip chart recordings gave essentially the same distributions as those illustrated here. *b*, The mean of the measured step sizes and the standard deviations plotted as a function of the holding potential. Numbers in brackets are the number of individual events analysed at each potential. The solid line is the least-squares fit to the mean value at each holding potential. The slope of this line was 133 pS. The zero current intercept was -2.5 mV. The recording conditions were the same as described in Fig. 1.

vertebrate muscle membrane have recently been made. The single channel conductance (about 25 pS) and kinetics correspond well with those inferred from noise analysis^{7,8}. We report here the measurement of the currents passing through individual glutamate channels in locust muscle. The conductance of an open single channel is about 130 pS. The gating kinetics are complex, and evidence is given for sudden changes in an individual channel's distribution of open and closed times.

Single glutamate channels have been measured on metathoracic extensor tibiae and retractor unguis muscles in adult locusts (*Locusta migratoria*) by placing a patch electrode containing low concentrations of glutamate against the surface of the cell. However, due to a low channel population density and rapid desensitisation of extrajunctional D receptors, these records were difficult to obtain and often contained less than 10 individual events. The population density of extrajunctional D receptors was increased by using muscles denervated for at least 6 d (refs 9-11). Nevertheless, even with denervated muscle, desensitisation was often complete before the patch electrode could be properly sealed against the membrane. Therefore, most studies were made on extrajunctional receptors of chronically denervated muscle which was pretreated with concanavalin A (Con A). Brief exposure of the cells to this lectin irreversibly prevents the desensitisation of junctional glutamate and extrajunctional glutamate D receptors on locust muscle^{12,13}. Pretreatment of the muscles with 1 μ M Con A in physiological saline for 15 min, followed by a thorough rinse, enabled us to make patch recordings which exhibited a stable level of channel activity for up to 30 min or longer.

Fig. 3 Complex kinetics of individual channels. *a*, A sudden kinetic state change in the activity record of what seems to be one channel. This record was made at the resting potential of this cell, -45 mV, without voltage clamp. The cell was from a 6-d denervated animal, and had been Con A treated. The mean channel open time before the transition was 2.8 ± 0.3 ms. After the transition it was 22.5 ± 4 ms. The probability that these events were from the same population, but distributed by chance, was $P < 0.001$. The mean closed times were 16.6 ± 2.1 ms, and 3.0 ± 0.5 ms, corresponding to a $P < 0.001$. *b*, a 6-s record of a channel's activity from a cell voltage clamped at -120 mV. The two segments

are contiguous. A broad variety of kinetic states are represented in this record. Note especially the long segment with a high frequency of fast activity, and the change to the ground state at the end of the segment. Both *a* and *b* were made by replaying pre-filtered data at a 60 times slower tape speed and recording on a normal strip chart recorder. f_c was 350 Hz. The reduced amplitude of some events was due to filter attenuation. Note the difference between the calibration scales in *a* and *b*. *c*, Histogram of the channel open times from the data segment in *b*. Open times were measured from digitised data as the time difference between the first downward deflection of the current and the next following upward deflection. All pattern recognition and signal-to-noise judgments were made by eye. Only transitions greater than 2–3 times the noise amplitude were measured. The data were unfiltered. The histogram was fitted with two exponentials using a non-linear, least-squares fitting program. The best fit was obtained with $\tau_{\text{fast}} = 1.8$ ms, $\tau_{\text{slow}} = 12.3$ ms and an amplitude ratio of 7.0. The normalised χ^2 for this fit was 1.0. *d*, Histogram of channel closed times made concurrent with *c*. The best fit was obtained with $\tau_{\text{fast}} = 1.6$ ms, $\tau_{\text{slow}} = 16.3$ ms, and an amplitude ratio of 6.2. χ^2 was 1.2.

Figure 1 shows glutamate channels in a 6-d denervated muscle which had been treated with Con A. The downward events are the sudden increase and subsequent decrease of inward currents. These currents are due to the opening and closing of individual channels. The current which flows through the open channel is essentially constant and depends on the membrane potential. At -60 mV, the approximate resting potential of the cell, this current is about 8 pA. At -120 mV, the single channel current is almost twice this value.

Single channel amplitudes are uniform in most cases. Uncertainties of measurement of these amplitudes are caused by the limited frequency response of the system and by the background noise, leading to some spread in the measured values. Figure 2*a* shows histograms of the channel currents at two different membrane potentials. The distribution centres roughly around a peak value, as in a gaussian distribution. Figure 2*b* is a plot of single channel current levels against membrane potential.

The conductance of the open channel seems to be independent of the membrane potential within the range of our measurements, as might be expected of a simple resistor. The points in Fig. 2*b* are fitted well by a straight line, whose slope corresponds to the conductance of the channel. The least-squares fit to the data points yields a line which has a slope of 133 pS and which has a zero-current potential very close to 0 mV. The extrapolated zero-current potential corresponds well with that of the miniature excitatory junctional currents (m.e.j.cs) in this cell. The m.e.j.cs have been shown to reverse at 0 to +5 mV, as do the responses to iontophoretically applied glutamate¹⁴.

The kinetics of the channel's open–close reaction are not stationary in these conditions. This inconstancy is most clearly observed during recordings where the frequency of the simultaneous opening of two or more channels (double events) is very low or zero. When two independent channels are open simultaneously within the measurement area the current measured should be double the normal current. The frequency of double

events is predicted by a binomial distribution, and for the high levels of activity illustrated here, this frequency is substantial. As few double events are observed, it is most probable that only one channel is active within the patch area. Recordings made in these conditions show that the channels can sometimes shift from one kinetic 'state' to another. Figure 3*a* shows one such transition. Both the mean open time and the mean closed time have suddenly shifted. Neither is likely to have come from the same exponentially distributed interval population found before the transition (see legend to Fig. 3). This segment is a small part of a recording lasting several minutes which contains virtually no double events. Transitions such as those in Fig. 3*a* occur very frequently in our records, and have been observed at several different membrane potentials.

Several different kinetic states have been observed in long records of what seems to be the activity of only one channel. The most common state is that shown in the beginning of the trace in Fig. 3*a*. In more than 90% of our measurements the activity was similar to that illustrated, that is, opening events with short (< 5 ms) durations, separated by relatively longer (> 20 ms) closed intervals. Histograms have been made of channel open times in long segments of data which seem to be only in this 'ground' state, and these open times are roughly exponentially distributed. However, the range of time constant values for the best fit exponentials vary from 1 to 3 ms, in many cases in identical conditions. These values are similar to those measured by noise analysis of the synaptic receptor kinetics and by the decay of m.e.j.cs⁵.

During records in which a channel's activity is not in the ground state, both the open and closed times are multi-modal. Figure 3*b* is an example of this type of activity. As was the case in the record shown in Fig. 3*a*, the number of double events was very low for several minutes before and after the illustrated record. Both the frequency of events and the event duration change many times during this segment, with an apparent return to the ground state at the end of the record. Figure 3*c* and *d* are

histograms of the open and closed intervals during this burst. Both histograms could only be adequately fitted by curves consisting of at least two exponentials. The lines shown are the least-squares fit to the data by double exponential curves. The various time constants are given in the legend to Fig. 3. The data indicate that the kinetics of this channel are the result of a complex process. Models of this channel's activity must take this into account. Furthermore, this multi-modal activity does not predict the relatively prolonged kinetic state changes observed in the channel's activity. These state changes must also be accounted for in a complete model of glutamate channel kinetics. It is not yet possible to determine whether the presence of Con A is responsible for the appearance of these multiple states. In several records made without Con A treatment, the channels seemed to be in the ground state. However, each of these records was too short, due to rapid desensitisation, to demonstrate the absence of other states without Con A.

In conclusion, direct measurement of the currents which pass through single glutamate-activated membrane channels in the locust muscle demonstrates that these channels have a conductance of about 130 pS and multiple kinetic states of channel gating. This conductance is almost five times larger than that of the ACh channels at the vertebrate neuromuscular junction, and is among the largest yet found in biological membranes. The measured conductance agrees well with that inferred from previous noise analysis in this system⁶. Our measurements also directly demonstrate that the conductance of the open channel is independent of voltage between -130 and -40 mV, and that the extrapolated reversal potential is very close to 0 mV, as has been suspected for this channel. We also measure a kinetic state of this channel which is very common, and which has a distribution of channel open times similar to those found for synaptic channels. Other kinetic states also occur in individual channels, often with sudden inter-state transitions. It has not been possible to determine if these states are also a property of the normal synaptic glutamate channel, or if they are induced either by the presence of Con A or by denervation. In either case, the observation that a single channel can suddenly change its kinetic properties is new, and must be investigated further. The patch electrode technique is the only method with resolution sufficient to clarify this problem further.

Effects of oxotremorine demonstrate presynaptic muscarinic and dopaminergic receptors on motor nerve terminals

THERE has been little conclusive evidence about the presynaptic effects of acetylcholine (ACh) and cholinomimetics on mammalian motor nerve terminals^{1,2} which may have functional implications in motor abnormalities^{3,4}. We now report the existence of dopaminergic muscarinic receptors on motor nerve terminals which participate in the local release of ACh from motor nerve terminals.

Details of the collection and assay of ACh released from isolated rat phrenic nerve into the bathing fluid have been given elsewhere⁵. Two samples (control and experimental) were collected from each preparation and assayed immediately (cross-over) on leech dorsal muscle, the bathing solution containing equivalent concentration(s) of the experimental drug(s). We also examined the effect of 0.5 μ M atropine on the action potentials of the phrenic nerve.

Oxotremorine sesquifumarate (Oxo-T)—a muscarinic agonist with no post-junctional effect on the diaphragmatic muscle⁶—induces transmitter release from phrenic nerve endings⁷ and thus serves as an excellent tool for studying the cholinergic presynaptic mechanisms at this site. The dose-dependent effect of Oxo-T in increasing ACh release and its prevention by preincubation with atropine (Table 1) demonstrate the presence of presynaptic muscarinic receptors on motor nerve terminals. Incubation with 0.5 μ M atropine alone

Fig. 1 Histogram showing: a, increase in ACh release caused by 10 μ M Oxo-T sesquifumarate; b, c, d and e, dose-dependent inhibition of a by dopamine hydrochloride (0.005, 0.02, 0.04 and 0.05 μ M, respectively); f, reversal of e in presence of 0.25 μ M pimozone; g, influence of 0.25 μ M pimozone on a. All values are normalised to the mean control ACh release during 15-min periods of electrical stimulation ($N = 4.05$ ng). Values represent means of at least six experiments $\pm$ s.e. One asterisk denotes significant increase from N ($P < 0.05$); two asterisks denote significant reduction from a ($P < 0.05$); three asterisks denote significant increase from e ($P < 0.05$). More than one symbol per bar indicates respective drug interactions. Black indicates Oxo-T; vertical hatching indicates dopamine, and cross hatching indicates pimozone.

Table 1 ACh released by different treatments

Treatment	ACh released (ng)
Control†	4.05 ± 0.73
Atropine sulphate, 0.5 µM	Not measurable (necessarily <1.25)
Oxo-T sesquifumarate, 2.5 µM†	135.14 ± 20.16*
Oxo-T sesquifumarate, 5 µM	208 ± 20.7*
Oxo-T sesquifumarate, 10 µM†	236 ± 33.12*
Atropine sulphate, 0.5 µM plus Oxo-T, 10 µM	Not measurable (necessarily <1.25)
Dopamine hydrochloride, 0.05 µM	4.0 ± 1.1
Dopamine hydrochloride, 5 µM	Not measurable (necessarily <1.25)
Pimozide, 0.25 µM	3.2 ± 0.42

Figures show ACh released, in the form of ACh chloride, into a 4-ml bath from rat phrenic nerve terminals in response to supramaximal stimulation (0.2 ms) at 1 Hz for 15 min in different experimental conditions. Values represent means of at least six experiments ± s.e. Concentrations of drugs are expressed in terms of molarity of the salts.

* Significant difference from control ($P < 0.005$).

† Data taken from ref. 3.

in control experiments inhibited the evoked ACh release to a level below the sensitivity range of our preparation (Table 1).

Dopamine hydrochloride by itself at 0.005–0.05 µM did not affect the normal evoked ACh release (Table 1), but it inhibited, as a function of its concentration, the increased release due to Oxo-T (Fig. 1). In the presence of a greater concentration of dopamine (5 µM), the normal evoked release of ACh was inhibited to a degree that could not be measured (Table 1).

The presence of dopamine receptors with an inhibitory influence on muscarinically (Oxo-T) mediated ACh release was demonstrated by reversal of the dopamine effect in the presence of 0.25 µM pimozide, a specific dopamine-receptor-blocking agent (Fig. 1). Incubation with pimozide alone, unlike atropine, did not affect the normal evoked and Oxo-T-induced release of ACh in control experiments (Table 1 and Fig. 1).

Our results demonstrate for the first time the presence of presynaptic dopaminergic muscarinic receptors on motor nerve endings. A function has been proposed for presynaptic muscarinic receptors at cholinergic sites in the brain⁵ and in the periphery⁶, apparently at variance with our findings. In such studies Oxo-T decreased ACh release and prevented the facilitatory effect of atropine. On the other hand, excess ACh release due to Oxo-T at both central and peripheral sites is well documented^{3,7–9}. Thus it is not clear whether the reported inhibition of ACh release by Oxo-T is mediated through a direct or an indirect mechanism. Indeed incubation with eserine inhibited ACh release from cerebral cortical slices^{10,11}.

The inhibition of normal evoked release of ACh by atropine, at a concentration that failed to affect phrenic nerve action potentials, indicated that the presynaptic muscarinic receptors participate in ACh release from motor nerve endings. Although a similar effect of atropine was reported earlier², its mechanism of action remained obscure. Our study raises the possibility that locally liberated ACh from motor nerve terminals activates the presynaptic muscarinic receptors, leading to further release. The inability of pimozide to increase normal evoked ACh release (Table 1) shows that the inhibitory dopaminergic sites on the motor nerve terminals do not normally influence transmitter release. This is expected because dopamine is not known to be liberated at this site. But in the light of our findings it seems plausible that systemic circulatory dopamine, more so in subjects receiving L-dopa therapy, must modulate ACh release from motor nerve endings, if not at cholinergic synapses in general. This presynaptic dopamine action may be of therapeutic significance because presynaptic cholinergic dominance at the neuromuscular junction and at the junction of motor axon collaterals and Renshaw cells in the spinal cord have been

clearly implicated^{4,12–14} in the 'Oxo-T-model'^{15,16} of parkinsonism. Indeed L-dopa pretreatment was found to protect Oxo-T-induced tremor to some extent^{17,18} and to inhibit the antidromically activated spike discharges of single Renshaw cells¹⁹. Our findings support the hypothesis of presynaptic modulation of ACh release by dopamine at cholinergic sites^{20,21}.

We thank Mr J. R. Vedasiromoni for help in preparing our manuscript.

Decreased content of immunoreactive enkephalin-like peptide in peripheral tissues of spontaneously hypertensive rats

THE dopaminergic modulation of neuronal transmission in coeliac ganglia of spontaneously hypertensive rats (SHR) has been shown to be less efficient than in control Wistar Kyoto rats (WKY). From these results it was inferred that the development of hypertension may be due to this defect. Recent reports^{2,3} suggest that polypeptides may function as neurotransmitters or neuromodulators in sympathetic ganglia. A heterogeneous group of immunoreactive Met⁵-enkephalin-like (ME) peptides have been found in these ganglia³, and are also present in adrenal glands, in both chromaffin cells and afferent axons (unpublished observations). Some of these peptides, when released from the afferent axons, may modulate opiate receptors located in adrenal medulla (unpublished observations). The vasodilatory action of morphine suggests that if the opiate agonists present in the chromaffin cells were to be secreted they might also cause vasodilation by acting on distant receptors. In view of their possible role in the regulation of sympathetic transmission and vascular tone, we have studied the content and chromatographic characteristics of the immunoreactive ME-like peptides in adrenal gland, sympathetic ganglia, salivary gland and hypothalamus of SHR and WKY rats. We report here

Table 1 The content of ME- and LE-like material in various tissues of WKY and SHR rats

Rat strain	Rat age (weeks)	Coeliac ganglion		Superior cervical ganglion	Salivary gland	Adrenal gland	Hypothalamus
		ME	LE	ME	ME	ME	ME
WKY	4	3.4±0.31 (7)	1.8±0.097 (7)	1.9±0.12 (7)	—	—	—
SHR	4	2.0±0.16* (8)	1.1±0.048* (8)	1.9±0.059 (8)	—	—	—
WKY	8	2.0±0.12 (15)	1.2±0.051 (10)	1.3±0.11 (5)	0.090±0.012 (5)	0.046±0.0081 (5)	3.7±0.14 (10)
SHR	8	0.95±0.028* (15)	0.68±0.030* (10)	0.78±0.20† (5)	0.045±0.010† (5)	0.020±0.004† (5)	3.3±0.17 (10)
WKY	12	1.7±0.14 (5)	—	1.4±0.081 (5)	—	—	—
SHR	12	0.93±0.082† (5)	—	0.93±0.18† (5)	—	—	—

Immediately after dissection, the ganglia were added to boiling 0.1 M CH_3COOH and heated for 3–5 min at 100 °C. The neutralised supernatant was then radioimmunoassayed for ME and LE. Adrenal, salivary glands and hypothalamus were treated by microwaves and extracted with 0.1 M CH_3COOH . Values are expressed as ng per mg protein. No difference was noted in the weights or the protein content of the various tissues from WKY or SHR.

* $P < 0.01$; † $P < 0.05$.

that the content of these peptides was lower in SHR than WKY rats in all tissues studied, except the hypothalamus. In sympathetic ganglia this decrease was due to a reduction in the ME content and not to that of the high molecular weight (MW) immunoreactive ME-like peptides.

Male 3-week-old SHR and WKY rats (Thaconic Farm) were reared in our animal facility in optimal conditions of illumination (12 h light/12 h dark), temperature (24 °C) and humidity. At various ages, an equal number of the SHR and WKY animals were killed by decapitation and exsanguinated. Table 1 shows that SHR already have a lower concentration of immunoreactive ME-like peptides in the coeliac ganglion at 4 weeks after birth, when the blood pressure of WKY and SHR rats is similar¹. Immunoreactive ME-like peptide content is also decreased (Table 1) at 12 weeks in the coeliac and superior cervical ganglia of SHR when their blood pressure is pathologically higher than that of WKY. Also, the coeliac content of Leu⁵-enkephalin-like (LE) polypeptides in SHR is smaller than that in WKY animals. The content of immunoreactive ME-like peptides in the adrenal and salivary glands was also significantly smaller in SHR than in WKY rats (Table 1). In contrast, immunoreactive ME-like peptide content in the hypothalamus was similar in 8-week-old SHR and WKY rats.

The various molecular forms of immunoreactive ME-like peptides present in sympathetic ganglia include a low MW polypeptide which has previously been shown to be immunologically and chromatographically indistinguishable from ME. We wondered whether in SHR animals there was a

reduced content of ME or of the immunoreactive ME-like high MW polypeptides. Therefore, we extracted the sympathetic ganglia with absolute alcohol which selectively solubilises a polypeptide which on thin layer chromatography behaves like ME, leaving the other high MW immunoreactive ME-like peptides undissolved. We found that a coeliac ganglion of a 12-week-old WKY rat contains about 0.27 ng ME, whereas the homologous ganglion of SHR rats contains only about 0.18 ng ME. A superior cervical ganglion of WKY and SHR contains 0.087 and 0.055 ng ME, respectively. The chromatographic profile of the immunoreactive ME-like peptides present in coeliac ganglia shows that the ganglia of SHR rats contain less of the low MW immunoreactive ME-like peptides but about an equal amount of the high MW immunoreactive material (Fig. 1). This abnormality is present in peripheral tissues but not in the hypothalamus (Table 1) or in the striatum (data not shown). The decrease of peripheral immunoreactive ME-like peptides may be due to a deficit in the enzyme that forms ME, an increase in the enzyme that catabolises ME or an increase in the rate of ME utilisation. Preliminary data from our laboratory^{3,4} indicate that the ratio of high MW immunoreactive ME-like peptides to ME in brain is much smaller than that in peripheral tissues, and we have also shown that the high MW immunoreactive ME-like peptide can release ME when subjected to controlled proteolysis (unpublished observations). Thus, it is possible that the mechanisms which synthesise ME in brain and in periphery differ and that the genetic defect in SHR rats which reduces the content of ME-like peptides in peripheral tissues may be an abnormality in ME biosynthesis. If this defect is an important cause of the hypertension in SHR animals, one could infer that ME-like peptides, like morphine, may lower the vascular tone. However, the nature, mechanism, site and pathogenetic significance of the defect in ganglionic ME-like peptides reported here remains to be investigated.

Fig. 1 Biogel P-2 column chromatography of sympathetic ganglia from WKY (a) and SHR (b) rats. Coeliac ganglia (30) and superior cervical ganglia (60) were extracted in 1 M CH_3COOH and heated for 5 min at 100 °C. The resulting supernatant was lyophilised, dissolved in 0.5 ml of 1 M CH_3COOH and chromatographed with Biogel P-2 column (0.9×60 cm) using 1 M CH_3COOH as the eluent. Aliquots of each fraction of the eluate were lyophilised and radioimmunoassayed with antiserum directed against ME. Two fractions appear, one of high MW, is eluted with the void volume (V_0), the other is eluted within the volume that is characteristic of ME. The exclusion limit of this column is 1,800 daltons.

Histamine receptors on rabbit blastocyst and endometrial cell membranes

DESPITE much study, the role of histamine in ovum implantation remains unclear¹⁻⁵. Histamine action is mediated by H_1 and H_2 receptors^{6,7}, which are widely distributed on the cell membranes of mammalian tissues⁸⁻¹⁴. However, no information is available about the histamine receptors on blastocyst or endometrial cell membranes. Recent evidence indicates that a certain lymphocyte subpopulation carries histamine receptors⁹ and has an important regulatory function *in vitro*¹⁰⁻¹² and *in vivo*^{12,13} in mice⁹⁻¹¹, guinea pigs¹² and man¹³. Murine T cells, capable of regulating antibody secretion *in vitro*¹⁰, and precursors of T cells, capable of mediating cytotoxic effector cells¹¹, carry histamine receptors. The density of these receptors increases with cell maturation¹¹. Cell activation by histamine results in increased levels of intracellular cyclic AMP¹¹ and production of small molecular weight material, called histamine suppressor factor, capable of suppressing both cell proliferation and lymphokine production by sensitised lymphocytes following exposure to the antigen¹². Histamine suppression of delayed hypersensitivity in guinea pigs *in vivo* can be blocked completely or partially by H_2 and H_1 antagonists, respectively¹². Also, the administration of H_2 antagonists to man results in enhancement of delayed skin tests¹³. These observations indicate that lymphocytes carrying H_2 receptors acquire immunosuppressor potential on activation.

We demonstrate here that 6-day rabbit blastocyst and uterine endometrial cells carry H_2 and H_1 receptors, respectively. The possible significance of H_1 and H_2 receptors in ovum implantation and in suppressing *in situ* maternal capacity to reject the implanting embryo carrying alloantigens are discussed.

Six-day blastocysts from superovulated¹⁵ domestic rabbits were recovered by flushing the uteri with chilled medium RPMI 1640 supplemented with bovine serum albumin (BSA). The blastocysts were washed twice in the same medium, transferred to a small disposable sterile Petri dish, ruptured and gently teased with a needle. The preparation was passed through a 25-gauge needle to obtain single-cell suspensions. Endometrial cells from the same animals were obtained by scraping off the uterine endometria with a scalpel blade. The scrapings were transferred to a sterile plastic tube containing BSA-supplemented cold RPMI 1640 medium. The clumps of endometrial cells were first passed through a 19-gauge needle and then a few times through a 25-gauge needle to obtain single-cell preparations. The blastocyst and endometrial single-cell suspensions were centrifuged at 720g, washed and resuspended in phosphate-buffered saline (PBS) with 10% fetal calf serum. Cell numbers were then counted and adjusted to 0.5×10^5 cells ml^{-1} . With this technique, less than 1% of cells were found to be dead by the standard Trypan blue exclusion method.

Histamine receptors were visualised by incubating single-cell preparations in fluorescein isothiocyanate-BSA-histamine (FITC-BSA-H) conjugate for 30 min at 4°C. FITC-BSA-H was prepared by conjugating 50.0 mg FITC-BSA (fluorescein-protein ratio, 3:1) to 350.0 mg histamine dihydrochloride (Calbiochem) in the presence of 1.0 g of 1-ethyl-3(3-dimethylaminopropyl)carbodiimide (ECDI; Story) at room temperature for 2 h followed by extensive dialysis at 4°C against 2 l of PBS for 48 h. In all the experiments, FITC-BSA-H was used at a dilution of 1:25 with PBS. Following incubation the cells were washed twice, mounted in PBS-glycerine mixture and examined under a fluorescence microscope using an epillumination system. Membrane stain was demonstrated as fluorescent speckles. The control cells, incubated in FITC-BSA in the absence of histamine, were negative. Moreover, red blood cells, as contaminants in the endometrial cell suspensions, did not

show any binding with FITC-BSA-H conjugate. The specificity of binding was determined by incubating cell suspensions in free histamine, chlorpheniramine (H_1 -receptor antagonist)¹⁶ and metiamide (H_2 -receptor antagonist)¹⁷ before incubation in FITC-BSA-H. Statistical analysis was according to Student's *t* test.

Figure 1a shows the results of histamine binding with blastocyst cell membranes: $37 \pm 11\%$ of blastocyst cells showed bright membrane fluorescence on staining with FITC-BSA-H. Histamine and metiamide, at both 10^{-4} M and 10^{-5} M concentrations, displaced the binding significantly ($P < 0.01$). Chlorpheniramine significantly displaced the binding only at 10^{-4} M ($P < 0.05$). Figure 1b shows the results of histamine receptor determinations on endometrial cell membranes: $21 \pm 9\%$ of endometrial cells showed binding with FITC-BSA-H conjugate and this binding was significantly suppressed by free histamine and chlorpheniramine at both 10^{-4} M ($P < 0.005$) and 10^{-5} M ($P < 0.05$). Metiamide, on the other hand, did not suppress the binding. None of the above agents at 10^{-6} M were able to alter the binding response of either blastocyst or endometrial cell membranes. The above results indicate that blastocyst cell membranes carry mainly H_2 receptors, whereas endometrial cells carry H_1 receptors.

Fig. 1 The blocking effects of histamine or various histamine antagonists on the binding of blastocyst (a) and endometrial (b) cell suspensions to FITC-BSA-H. Results shown are means $\pm$ s.d. of several experiments. The number of experiments is shown in parentheses. Asterisks denote a significant difference from binding values in the absence of a blocking agent. Rabbit blastocyst or endometrial cell suspensions (0.5×10^5 in 1.0 ml of RPMI 1640) were incubated for 30 min at 4°C with 0.1 ml of various concentrations of the blocking agents, histamine, anti H_1 (chlorpheniramine) or anti- H_2 (metiamide). They were washed three times in chilled medium, stained by incubating them with FITC-BSA-H at 4°C for 30 min and then washed and mounted. In all experiments at least 200 cells per slide were counted.

The mammalian blastocyst is composed of two types of cell: the inner cell mass and trophoblast. Similarly, the endometrium is composed of epithelial, stromal and glandular cells. Our findings do not indicate the cell type in the blastocyst or endometrial that carries histamine receptors. The observation that histamine receptors could be detected on some of the blastocyst or endometrial cells is not unique; human blood lymphocytes are also heterogeneous and only $30 \pm 3.8\%$ of these cells can bind to histamine¹⁸.

Further work is necessary to elucidate the possible role of histamine receptors in blastocyst-endometrium metabolism, implantation and acceptance of the blastocyst allograft by the maternal tissues¹⁹. Despite many suggestions, it remains a challenge to reproductive biologists and immunobiologists to explain the escape of the embryo from the immunological responses of the mother¹⁹. In an immunologically competent system, histamine binding to H₁ receptors mediates a variety of pro-inflammatory events, such as increased permeability and vasodilatation, whereas histamine activation of H₂ receptors mediates several immunosuppressive effects through stimulation of cyclic AMP synthesis¹¹. A local inflammatory reaction, accompanied by accumulation of histamine in the uterus, occurs around the time of implantation²⁰. Implantation in the rabbit begins within 6½–7 d of pregnancy (day 1 = 24 h post coitum)²¹, and the cyclic-AMP/cyclic GMP ratio in the rabbit blastocyst changes before implantation²². Moreover, cyclic AMP has been shown to participate in blastocyst implantation in the mouse^{23,24}. The above bimodal function of histamine through H₁ and H₂ receptors is feasible, as systemic administration of either H₁ or H₂ receptor blockers in rats has no effect on preimplantation stages of pregnancy, whereas the combination of the two interferes with implantation²⁵. Furthermore, histamine involvement in inducing implantation in mice or rats during delayed implantation^{26,27}, and interruption of implantation in rabbits by inhibition of uterine histamine release have been reported recently²⁸. Also, 6-day rabbit blastocysts have been shown to suppress the mitogen response of autologous splenic lymphocytes *in vitro*²⁹. It remains to be seen whether this suppressor activity of blastocysts is mediated through activation of histamine receptors.

We thank Mrs Marilyn Ousley and Mr Terrill Smith for technical assistance, Mrs Anne Scott for typing the manuscript, and Dr John G. Paul (Smith, Klein and French) for supply of chlorpheniramine and metiamide. This research was supported in part by NIH Biomedical Research Support grants 5 S01-RR-5373 and HD-12304, and Mid America Cancer Center Program.

Early pregnancy factor is immunosuppressive

IMMUNOSUPPRESSION during pregnancy has important consequences not only with respect to the recognition of the antigenically dissimilar embryo¹ but also in terms of susceptibility to viral or tumour assaults^{2,3}. We have recently described an early pregnancy factor (EPF) detectable within 24 h of mating and have postulated that this protein is responsible for depression of lymphocyte activity during pregnancy^{4–6}. Immunosuppressive properties have been attributed to other proteins detectable during pregnancy. These include pregnancy-associated macroglobulin^{7,8}, α -fetoprotein⁹ and human chorionic gonadotropin (HCG)^{10,11}. One characteristic these substances have in common, but in which they differ from EPF, is that they are not present, or not detectable, in the early stages of pregnancy. Recently the immunosuppressive activity of HCG has been disputed by several workers working with highly purified material^{12,13}. We have now shown that EPF inhibits the expression of an immune response *in vivo*.

After fertile matings, EPF has been detected on the lymphocytes and in the serum of mice, humans and sheep within 6–24 h and has been shown to be present for approximately the first two trimesters of pregnancy^{4–6}; EPF activity was not detected after sterile matings in any of the three species (refs 4, 6, B. Fitzgerald, personal communication). This substance was found in serum in two different forms, one of apparent molecular weight 200,000–240,000 detectable from 5 h after mating, and the other, ~50,000 MW detectable from 6 d after mating¹⁴.

The rosette inhibition test has been used as the assay method for the detection of EPF. This test was originally used to assess the immunosuppressive activity of anti-lymphocyte serum (ALS)^{15,16} and the results showed that the rosette inhibition titre (RIT) of each serum did not vary significantly using lymphocytes from different normal donors. If the lymphocytes were from pregnant donors, or had been incubated in serum from pregnant donors, the RIT of the ALS was significantly increased^{4–6}. This was a novel use of the rosette inhibition test and, on the basis of the ALS-sparing properties of EPF, we proposed that EPF is immunosuppressive. The use of an *in vivo* test, however, would clearly establish this point. We have now used the technique of adoptive transfer of contact sensitivity to trinitrochlorobenzene (TNCB) by lymphoid cells from sensitised mice^{17,18}. Lymph node cells, taken 4 d after sensitising mice with TNCB, were incubated with EPF preparations from pregnant sheep (Table 1), before injection of these cells into naive syngeneic mice. Skin tests for delayed-type hypersensitivity were immediately performed on the recipients¹⁹.

Serum or serum fractions having EPF activity (Table 1) suppressed the adoptive transfer of contact sensitivity (Table 2). When TNCB-sensitised lymph node cells were incubated with 24-h pregnant sheep serum (EPF I, Table 1), the ability of these

cells to transfer TNCB sensitivity was completely abolished (Table 2, experiment 1). Partial suppression of activity was observed when cells were preincubated with normal sheep serum, but significant transfer of activity was still achieved. Preincubation with the high MW fraction (EPF II, Table 1) also abolished transfer of TNCB sensitivity, whereas the use of the corresponding non-pregnant sheep serum fraction (control II) had no effect (Table 2, experiment 2). Two preparations of the low MW fraction prepared from 24-h pregnant sheep serum (EPF IIIa and EPF IIIb, Table 1) completely suppressed adoptive transfer, compared with normal serum controls. Although one of these controls (control IIIa) gave a slight decrease in reaction, there was still a significant transfer of sensitivity. Control IIIb gave a result not significantly different from that obtained with the cells incubated in medium alone (Table 2, experiment 3). A preparation of the low MW fraction obtained from the serum of 1-2-month pregnant sheep (EPF IV, Table 1) completely abolished adoptive transfer, whereas the corresponding fraction from normal serum (control IV) had no significant effect (Table 2, experiment 4).

In these experiments we have shown that EPF inhibits the expression of an immune response *in vivo*; the suppressive effect demonstrated was not species specific as sheep EPF inhibited the activity of mouse lymphocytes. Previously EPF activity had been detected using the rosette inhibition test and, although this test had proved convenient and very accurate, its role as a measure of immunological function was still debatable. The demonstration that EPF can completely suppress the adoptive transfer of contact sensitivity, well established as an immunological process, clearly indicates that EPF is immunosuppressive *in vivo*. The indirect technique of adoptive transfer was used, as preliminary experiments involving the injection of sheep EPF directly into mice, both before and after sensitisation, indicated

Table 1 Preparation of serum and serum fractions containing EPF

Source	EPF I Whole serum (24 h)	EPF II Serum fraction (24 h)	EPF III DEAE- Sephadex treated serum (24 h)	EPF IV Serum fraction (1-2 mth)
Approximate MW	240,000	240,000	50,000	50,000
Rosette inhibition titre	28	24	(a)24 (b)22	26

EPF I, pregnant sheep serum, taken 24 h after mating, was inactivated at 56°C for 30 min, and the rosette inhibition titre (RIT) determined by the method described previously¹⁰. Serum taken from a nonpregnant ewe was similarly treated (control I). EPF II, pregnant sheep serum, as above, was fractionated on an Ultrogel AcA34 (LKB) column¹⁴ and tested for EPF activity by the RIT. The fractions that contained the EPF activity in the region of MW 240,000 were pooled, dialysed against Hank's balanced salt solution (HBSS) and concentrated to 1/5th of the original serum volume. The RIT of the preparation was determined before use. Nonpregnant ewe serum was similarly processed (control II). EPF IIIa and EPF IIIb, serum was collected from two pregnant ewes, 24 h after mating. Thirty ml of each were partially purified with DEAE-Sephadex A50 (Pharmacia), which removed the macroglobulin and albumin fractions of the serum proteins, then dialysed against HBSS and concentrated to 1/5th of the original serum volume. Before use, the RIT of these preparations was estimated and they were fractionated to determine the MW of the EPF activity¹⁴. Serum from two nonpregnant ewes was similarly treated (control IIIa and IIIb). EPF IV, serum was collected from pregnant sheep 1-2 months after mating and applied to an Ultrogel column. The fractions, MW ~50,000, which had EPF activity, were pooled, dialysed against HBSS and concentrated to 1/5th of the original serum volume. Control IV was nonpregnant ewe serum run in parallel.

* The rosette inhibition titre (RIT) is expressed as the logarithm (base 2) of the reciprocal $\times 10^{-3}$ of the highest dilution of anti-lymphocyte serum (ALS) to inhibit the rosette formation to 75% or less than that of control test (cells in HBSS alone). RIT obtained using serum from non-pregnant sheep: mean = 9.8, s.e.m. = 0.3, n = 20.

Table 2 Suppression of adoptive transfer of contact sensitivity by EPF

Expt	Cells transferred [†]	Cells preincubated with [†]	No of recipient mice	Skin test [‡] 24 h ear swelling ± s.d. (cm $\times 10^{-3}$)

	130 $\times 10^6$	Control IIIb	5	9.6 ± 2.6	P < 0.01
	130 $\times 10^6$	EPF IIIb	5	5.8 ± 1.9	P < 0.01
4	None	-	6	4.3 ± 1.0	
	80 $\times 10^6$	-	5	9.4 ± 3.5	P < 0.001
	80 $\times 10^6$	Control IV	4	7.5 ± 2.4	P < 0.001
	80 $\times 10^6$	EPF IV	5	4.6 ± 1.6	P < 0.001

* Auxiliary and inguinal lymph node cells taken from CBA mice 4 d after skin painting with 7 mg TNCB in 0.1 ml acetone¹⁵ were washed three times in culture medium and preincubated at 50×10^6 cells ml⁻¹ in reaction mixture as indicated.

† Experiment 1: cells were incubated at 37°C for 60 min in Eagle's basal medium containing 10% fetal calf serum (Commonwealth Serum Labs) and 50% control I or EPF I (Table 1). Cells were washed twice in culture medium, suspended in saline and injected intraperitoneally (0.2 ml) into the recipients (CBA mice). Experiment 2: as above, but reaction mixture contained 20% of control II or EPF II (Table 1). Experiments 3a and 3b: as above, but reaction mixture contained 20% of control IIIa, EPF IIIa, control IIIb or EPF IIIb (Table 1). Experiment 4: as above, but reaction mixture contained 20% of control IV or EPF IV (Table 1).

‡ Within 1 h of cell transfer, both ears of control and recipient mice were measured using an engineer's micrometer (Mitutoyo) and painted with 10 μ l of a 1% solution of TNCB in acetone. After 24 h the ear thickness was again measured and ear swelling determined by subtraction.

that immunosuppression was partially obscured by the effect of heterologous protein.

Adoptive transfer of contact sensitivity and inhibition of rosette formation are both T-cell dependent^{16,17}. As EPF affects both of these reactions, its primary function in protecting the fetus may be directed towards a depression of T-cell activity in the maternal system. We may speculate that EPF might protect the mother from immunological attack by the fetus. EPF has been detected in the fetal tissues (H.M. *et al.*, unpublished observations), which suggests another possible role for EPF, namely in the regulation of the development of the fetal immune system. The mechanism of action of EPF is still far from clear; its action is obviously not antigen specific and not even species specific. Whether it is suppressive by simply coating lymphocyte surfaces and preventing antigen presentation, or by a more active method, is yet to be established.

Myosin as a constituent of the *Drosophila* egg cortex

MYOSIN and actin have been found in many cell types, including the eggs of Amphibia¹, sea urchins², starfish³ and rats⁴. Their distribution correlates well with the distribution of microfilaments in structures such as the contractile ring, and these proteins are believed to have a major role in cell cleavage and plasmalemma elongation⁵. They have not previously been recorded in *Drosophila* eggs and embryos. The egg of *Drosophila* develops as a syncytium with about 6,000 nuclei present in a common cytoplasm⁶. Subsequently, nearly all the nuclei are simultaneously surrounded by plasmalemmas which grow down into the cortex of the egg. Because of this, and because of the existence of several mutants which specifically affect cellularisation^{7,8}, *Drosophila* eggs are a particularly appropriate system in which to study cell membrane formation. The simultaneous

Fig. 1 Precipitin bands against 20 μ g fly flight muscle in 2% SDS and 60 mM Tris-HCl, pH 6.8 (M), and 80 μ g of an extract of locust oocytes (O). The extract was obtained by homogenising in 1.2 M KCl, 15 mM Na pyrophosphate and 15 mM Tris-HCl, pH 7. The 50% $(\text{NH}_4)_2\text{SO}_4$ cut was dissolved in 0.6 M KCl, 2 mM dithiothreitol (DTT), 2 mM ATP and 15 mM Tris-HCl and dialysed against 0.25 M KCl, 2 mM DTT, 2 mM ATP and 15 mM Tris-HCl, pH 7. The precipitate was dissolved in 2% SDS and 60 mM Tris-HCl, pH 6.8. Ouchterlony plates contained 2% Noble's agar, 0.5 M NaCl, 0.01 M phosphate buffer, pH 7.5, 0.1% SDS and 0.5% Triton and were left for 4 d at 4°C before washing for 2 d in 0.6 M KCl and 20 mM Na pyrophosphate, pH 7, 1 d in 0.8% NaCl, followed by drying down and staining. 'A' marks the antiserum well.

Fig. 2 Crossed immunoelectrophoresis to demonstrate antibodies against myosin. *Sarcophaga* flight muscle myosin (14 μ g) was electrophoresed on a tube gel with SDS by the method of Weber and Osborn¹⁴. Electrophoresis in the second dimension was by the method of Converse and Papermaster¹⁵. A strip (1 mm thick) from the SDS gel was electrophoresed into 1% agarose; the layer of agarose (0.5 cm wide) next to the SDS gel contained 0.5% Tween and the rest of the agarose contained 2% IgG from antiserum. The stained SDS gel is heavily loaded to show minor bands. H indicates the heavy chain of myosin, L the light chains, and A contaminating actin.

cellularisation of the whole of the egg cortex would seem to require the existence of large numbers of microfilaments but these have not yet been visualised in the electron microscope⁹. We report here the finding of a continuous band of myosin immediately below the egg plasmalemma which could well be associated with massed microfilament bundles. This is laid down by the time of fertilisation and remains continuous until the arrival of the nuclei in the cortex. The structure of the band and its relationship to early developmental events are described.

Fig. 3 Freshly dissected *Drosophila* flight muscle myofibril decorated with anti-myosin at a final concentration of 2 mg ml⁻¹. Decoration technique as for embryo sections. Arrow indicates Z line. Scale bar, 3 μ m.

Antibodies were made against *Sarcophaga* (blowfly) flight muscle myosin. Myosin was prepared by the method of Bullard and Reedy¹⁰, and further purified by running on 5% SDS-acrylamide slab gels. The band containing the heavy chain of myosin was identified, cut out, homogenised with four volumes of phosphate-buffered saline (PBS) plus 0.5 ml Freund's adjuvant, and injected into white New Zealand rabbits. The total volume was about 3 ml. A total of 1 mg of myosin heavy chain was injected in three equal fortnightly injections. The rabbit was bled 1 week after the last injection. IgG was purified from the antiserum following the method of Campbell *et al.*¹¹. This antiserum gave a single band when tested in Ouchterlony plates (Fig. 1). It also reacted with an extract of locust oocytes containing a putative myosin as a major component. The fusion of the precipitin arcs formed with muscle myosin and oocyte extract shows that the antigens in these preparations had common antigenic sites. This situation is like that of the starfish, where antiserum against egg myosin reacts with tube foot muscle myosin¹². The specificity of the antiserum was further tested in crossed immunoelectrophoresis. A large rocket was obtained

Fig. 4 Sections of 1 nucleus stage *Drosophila* embryos decorated with anti-myosin IgG. In both cases the same section is seen under epifluorescence (a, c) and phase contrast (b, d). a And b show the sidewall running obliquely into the anterior tip region, c and d show the posterior pole. In c and d the brightly fluorescent structure at upper right is the autofluorescent vitelline membrane. Scale bar, 5 μm .

opposite the myosin heavy chain (Fig. 2). Our antiserum binds to A-bands of *Drosophila* flight muscle myofibrils giving patterns similar to those described by Garrett for *Lethocerus* flight muscle myofibrils¹³ (Fig. 3).

Sections of embryos were prepared by a modification of Sainte-Marie's method¹⁶. All procedures except for embedding were carried out at 4 °C. Fixing was done for 1 h using a 6 : 16 : 22 mixture of formaldehyde : ethanol : distilled water. The embryos were carefully punctured to allow adequate penetration of the fixative. They were then dehydrated by passing through each of the following solutions for 30 min: 70% ethanol, 90% ethanol, absolute ethanol and isopropanol (two changes). Clearing was accomplished using ligroin (BDH) for 1 h. The embryos were embedded in paraplast and sectioned at 5 μm .

The technique very effectively preserves delicate structural features such as the cleavage furrows. Sections were treated with either anti-myosin IgG or IgG from the same rabbit before immunisation, using a final concentration of 2 mg ml⁻¹ in buffered saline in both cases. They were incubated at 37 °C for 1 h and then washed for 15 min with PBS, pH 9.5. Results were complicated by nonspecific fluorescence for some pre-immune sera. This was reduced by using a pH 9.5 wash as recommended by Bennett *et al.*¹⁷. Fluorescein isothiocyanate-conjugated sheep anti-rabbit IgG (Wellcome) was added as the second part of the sandwich at a concentration of 0.8 mg ml⁻¹ in PBS and incubated and washed as before. Sections were mounted in a 9 : 1 mixture of glycerol : 1 M Trizma base, pH 9. Microscopy was carried out with a Zeiss standard R microscope equipped with an epifluorescence attachment and a Planapo lens ($\times 63$ NA 1.4).

The results show the existence of a continuous band of fluorescence immediately below the cell membrane, extending around the whole egg (Fig. 4). Controls show no such band, only background fluorescence. Below the band more diffuse material extends deeper into the cortex. Analysis of photographs from 18 embryos (1 nucleus to 32 nuclei stages), indicated a thickness of

1.00 μm (s.d. ± 0.15 μm). This figure is apparently constant all along the sidewall. Towards the posterior pole (Fig. 4c, d) it gradually thickens to give a maximum of 1.59 μm (s.d. ± 0.15 μm). The posterior pole is associated with a considerable development of microvilli, which also show fluorescence. At the anterior pole the band thickens to 1.5 μm (s.d. ± 0.11 μm) but this is associated with a smaller development of microvilli (Fig. 4a, b).

The myosin band seems to be unlike the whorl-like masses of microfilaments in the amphibian cortex¹, but similar to the cortical distribution of myosin in rat oocytes⁴. What may the functions of the band be? We have evidence that once the nuclei arrive in the cortex this band of material breaks up and parts of it becomes associated with each nucleus. It subsequently becomes involved in the formation of cell membranes around the nuclei (R. W., R. Magrath and B. B., in preparation). It therefore seems reasonable to propose that one function of the epicortical myosin band is as a store of materials required in cell membrane formation. There is no simple explanation for the thickenings of the band at the anterior and posterior poles. At the posterior pole, the thickening may be partly concerned with the formation of a double layer of cells, the pole cells and the underlying somatic blastoderm cells. However, this does not explain the increased thickness at the anterior pole.

We thank Alba Warn, Adrian Thompson, Ruth Magrath and Joanna Bell for technical help.

The topography of the purple membrane

THE purple membrane of *Halobacterium halobium* functions as a light-driven proton pump^{1,2}. It is about 45 Å thick³ and contains a single polypeptide chain comprising about 240 amino acids⁴. Retinal is covalently attached to a specific lysine residue⁴ and has been implicated in the absorption of incident light energy². The retinal lies at an angle of about 20° to the plane of

the bilayer⁵. Seven protein rods running through the membrane, probably α -helices, have been detected by electron diffraction^{6,7}. Circular dichroism studies indicate a 75% helical content which is consistent with a seven-helix model⁸. A structure containing seven such α -helices requires about 210 amino acids to cross a membrane 45 Å thick seven times, thus implying that most of the polypeptide chain is buried in the lipid bilayer. Digestion of the membrane with proteolytic enzymes supports this view and only three parts of the polypeptide chain are apparently exposed. Here, we show by sequence analysis of digestion products that a section corresponding to the N-terminal seven residues is removed by pronase and proteinase K.

In common with pepsin and papain⁹, pronase and proteinase K also split at several internal sites¹⁰ in the region of residues 71–76 in the sequence of the polypeptide chain (Fig. 1), thereby removing a small segment. A third digestion site for these enzymes is in the region of the C-terminus. Trypsin, which does not split the chain internally, liberates into solution a 21-residue peptide from the C-terminus (residues –1 to –21 in Fig. 1) but does not split the bond between residues –23 and –24. Thus, 21 residues at the C-terminus are exposed to the aqueous environment.

We have determined the amino acid sequence of the N-terminal 83 residues and C-terminal 39 residues containing these three exposed regions (Fig. 1). We note four differences between our results and those published elsewhere¹⁰. These are listed in the legend to Fig. 1. The N-terminal segment is very hydrophobic, and taken in conjunction with the results of the protease digestions of the membrane above, suggests that a section of 63 amino acids—residues 8–70—is buried in the lipid bilayer. The remaining problem is to decide how this buried segment crosses the membrane and whether a structure consistent with the seven-helix model can be proposed. The most

Fig. 1 The amino acid sequence of the N-terminal and C-terminal regions of bacteriorhodopsin. Peptides were derived from digests of the protein with trypsin (T), thermolysin (Th), chymotrypsin (Chymo), cyanogen bromide in 80% formic acid (CB), cyanogen bromide in 88% formic acid and heptafluorobutyric acid (Wm)¹¹. Enzyme digests were carried out on succinylated protein in 0.5% ammonium bicarbonate, and chemical cleavages on delipidated protein. In addition, the linkage between residues 37 and 38 was cleaved specifically by incubation of delipidated protein in 70% formic acid at 37 °C for 48 h. The pyroglutamyl moiety was removed in 70% yield from succinyl protein by incubation for 30 h at 37 °C with pyroglutamyl amino peptidase (Boehringer) with a substrate: enzyme ratio of 50:1. The peptide PK was obtained from a digest of the membrane with proteinase K (4 h, 37 °C). T1 was liberated from the membrane by tryptic digestion. Peptide Th was isolated according to Bruton and Hartley¹². Wm, CB3, CB4, Chymo 1 and Chymo 2 by paper electrophoresis and chromatography. CB1, CB2, CB5, DP and PK by gel filtration of the digests in 70% formic acid on Biogel P-30. The sequences of Pyr, DP, PK, CB1, CB2 and CB5 were obtained with the aid of a spinning cup sequencer¹³ and CB1, CB2, CB3 and CB4 with a solid phase sequencer after coupling to amino-propyl glass¹⁴. Th was sequenced by mass spectrometry, Wm, Chymo 1, Chymo 2 and T1 by the dansyl-Edman procedure¹⁵. Ovchinnikov *et al.*¹⁶ found threonine at position 47, serine at –35, serine at –23 and glutamic acid at –14.

Fig. 2 Amino acid sequence of residues 50–70 plotted on a helix surface with 3.5 residues per turn. Sequence reads downwards right to left as if projected on to a sheet of paper wrapped twice round the helix axis and then unrolled. Each residue appears twice. Hydrophobic residues are circled. The box represents a relatively hydrophilic groove on the helix surface. This is consistent with a helical structure¹⁸.

probable interpretation is that the polypeptide crosses the membrane twice in two helices. Prolines at 8 and 37 are consistent with the notion that residues 9–34 (25 amino acids) form a helix which would span a distance of approximately $25 \times 1.5 \text{ \AA} = 37.5 \text{ \AA}$. This section is terminated by the sequence -S-D-P-D (residues 35–38) which could readily form a β -turn. Residues 39–70 would then cross the membrane a second time, emerging from it at about residue 70. This segment can be considered in two parts: residues 39–49, containing the retinal binding site, and the section between proline residues 50–70. It is likely that this latter section also forms an α -helix. This view is supported by plotting this sequence on a helix surface (Fig. 2). This shows a groove composed of amino acids with less hydrophobic side chains, a feature characteristic of an α -helix¹⁸.

Fig. 3 Proposed topography of N-terminal region of the purple membrane protein. Sections A (residues 1–7) and F (71–76) are accessible to proteolysis. B (residues 8–34) is probably an α -helix, C (residues 34–38) is a β -bend. D (residues 39–49) contains the retinal binding site, E (residues 50–70) may be an α -helix. The angle between the axes of D and E is not considered here. Proline residues occur at positions 8, 37, 50, 70 and 77.

The second helix (residues 50–70, E in Fig. 3) would be about 30 Å long and thus too short to cross the membrane. Hence, residues 39–50 containing the retinal binding site (D in Fig. 3) must partly cross the membrane. The secondary structure of this segment is rather uncertain but it too may be partly α -helical. These features are summarised in Fig. 3. Note that this model places all charged residues near the periphery of the membrane and that none are buried in the interior.

Our model places the N-terminus and loop F on the same side of the membrane. The retinal binding site is near to the opposite side. This is in contrast to earlier models which place loop F on the opposite side from the N-terminus and the retinal lysine variously midway between the two sides of the membrane or near the same side as the N-terminus surface^{9,17}.

Moreover, it has been suggested that the C-terminus is orientated towards the inside of the bacterial cell, and hence in a structure of seven helices it would be outside¹⁰. If this is so the retinal lysine will be near the inside surface of the membrane and loop F will be on the outside.

We thank R. Henderson and A. D. McLachlan for discussions and H. R. Morris for mass spectrometry of N-terminal peptide, Th.

Note added in proof: Recently, Gerber *et al.*¹⁹, using a somewhat different methodology, have determined sequences covering essentially the same regions of the polypeptide chain of bacteriorhodopsin as described here.

Globin gene deletion in HPFH, $\delta^0\beta^0$ thalassaemia and Hb Lepore disease

THE thalassaemias are a group of inherited disorders characterised by the defective production of either α (α thalassaemias) or non- α (β and $\delta^0\beta^0$ thalassaemias) globin chains of haemoglobins (Hb)¹. In β thalassaemias the decreased synthesis of β -globin chains is only partially compensated by the increased production of γ chains, which probably reflects² the massive hypertrophy of the erythron with selective survival of the clones of adult haemoglobin F-producing cells (F cells^{3,4}). The situation is very different in other genetic disorders of the non- α gene cluster, known as $\delta^0\beta^0$ thalassaemias and Negro type of hereditary persistence of fetal haemoglobin (HPFH). In these two forms there is a genuine increase of γ -chain production, as shown by the high level of HbF found in heterozygotes. Although a clearcut distinction from both the clinical and haematological point of view cannot be traced between these two forms, the HPFH differs from the $\delta^0\beta^0$ thalassaemia in having a higher degree of γ -chain synthesis and a more homogeneous distribution of HbF within red cells. Recently, it has been possible to carry out gene analysis on DNA prepared from β^0 , $\delta^0\beta^0$ thalassaemic and HPFH patients. The β -globin gene is present in β^0 thalassaemias^{5–9}, but in $\delta^0\beta^0$ thalassaemias and HPFH a major deletion, possibly involving both δ and β genes, has been demonstrated by hybridisation studies^{8,10–12}. To characterise the molecular defect in these genetic disorders more precisely, we have hybridised DNA from homozygotes with HPFH, $\delta^0\beta^0$ thalassaemia and Hb Lepore disease (in which non- α -chains are a $\delta\beta$ fusion product¹³). For this we used a pure full-size cDNA _{β} probe and specific 5' end and 3' end cDNA fragments (we designate as 5' end cDNA the portion corresponding to the 5' end of the mRNA; the same for the 3' end). Our results, reported here, show that in contrast to HPFH, where a complete δ and β gene deletion occurs, in $\delta^0\beta^0$ thalassaemia a 5'-end fragment of the δ gene is present.

Figure 1 shows the titration of β -globin sequences in DNA from a normal human, a case of Hb Lepore, a southern Italian patient with newly discovered $\delta^\circ\beta^\circ$ thalassaemia and two patients with HPFH, Negro type (all homozygotes). The cDNA $_\beta$ probe used was a full-size β band eluted from an agarose gel (see legend to Fig. 1), further purified to over 98% (not shown) by hybridisation with mRNA followed by hydroxyapatite (HAP) chromatography⁵. With HPFH DNA no hybridisation could be obtained (except at high cDNA-DNA ratios, when minor contaminating sequences are expected to hybridise^{14,15,22}), in agreement with Orkin *et al.*²³; in contrast, $\delta^\circ\beta^\circ$ and Lepore DNA showed a plateau level corresponding to approximately 25–30 and 30–40%, respectively (over the background HPFH DNA), of the hybridisation obtained with normal DNA. These data suggest that part of the $\delta\beta$ sequences are retained in $\delta^\circ\beta^\circ$ DNA.

To locate the residual fragment we used 5'-end and 3'-end cDNA probes. A 142-nucleotide long 5'-end fragment (nucleotides 81–222 (ref. 21)) of the β -globin sequence was obtained by digesting the full-size β -globin band with *Hae*III and eluting the heaviest fragment (H1 (ref. 21)) from a preparative polyacrylamide gel. This fragment was further purified from an identical size (141 nucleotides) α sequence²⁴ by hybridisation

Fig. 1 *a*, Hybridisation of full-size cDNA $_\beta$ to normal, Lepore, $\delta^\circ\beta^\circ$ and HPFH DNA in cDNA excess^{5,14,15}. cDNA was copied with avian myeloblastosis virus reverse transcriptase in the presence of actinomycin D from globin mRNA from an HbH disease (α thalassaemia) patient, as described previously¹², except that ³²P-dCTP (Amersham, 400 Ci mmol⁻¹) was 300 μ M, and incubation was carried out at 41 °C for 45 min. The cDNA was then separated from unreacted nucleotides by G50 chromatography, incubated with 0.3 M NaOH at 37 °C for 15 min to break the RNA, neutralised and ethanol precipitated with 40 μ g ml⁻¹ carrier *Escherichia coli* tRNA, pelleted, resuspended in 10 μ l of 1/10 E buffer¹⁶ containing 0.04% bromophenol blue, and electrophoresed at 120 V on a 2% agarose slab gel (15 cm $\times$ 15 cm $\times$ 0.2 cm) in E buffer, until the dye was 1 cm from the bottom of the gel. The gel was then autoradiographed using a Kodak Royal X-0 Mat X-ray film and the heaviest radioactive band (full-size cDNA $_\beta$ (ref. 20)) eluted electrophoretically from slices cut from the gel using the developed film as a reference. All DNAs were prepared by a HAP procedure¹⁷ and fragmented to 200–300 nucleotides by boiling for 20 min in 0.3 M NaOH (ref. 18). Normal and Lepore DNA were from the spleens of an anaemic non-thalassaemic patient and a Lepore Boston disease homozygote, respectively. HPFH DNA 1 was from white blood cells from the recently described homozygote found in Ghana¹⁹ and HPFH DNA 2 was from cultured fibroblasts from the Baltimore homozygote¹². $\delta^\circ\beta^\circ$ thalassaemic DNA was from white cells from a newly diagnosed southern Italian patient. DNAs (10–50 μ g) were mixed with increasing amounts of the full-size cDNA $_\beta$ probe in 0.12 M Na phosphate buffer, pH 6.8, 1 mM EDTA, at a DNA concentration of 5 mg ml⁻¹. The aliquots were sealed in silicon-coated glass capillaries, boiled for 10 min and incubated at 70 °C for 4,400 min. At the end of the incubation, the samples were assayed for S₁ nuclease-resistant radioactivity as described elsewhere⁵. The amount of cDNA $_\beta$ hybridised is converted to pg cDNA $_\beta$, and corrected for the background S₁ nuclease resistance (0.6%). Control experiments with cDNA $_{\alpha\gamma}$ show that all these DNAs hybridise identically. Normal, $\bullet$; Lepore, $\blacksquare$; $\delta^\circ\beta^\circ$ thalassaemia, $\circ$; HPFH 1, $\square$; HPFH 2, $\diamond$. Hybridisation of 5' cDNA $_\beta$ fragment (*b*) and 3' cDNA $_\beta$ fragment (*c*) to normal, Lepore, $\delta^\circ\beta^\circ$, HPFH 1 and HPFH 2 DNA. Full size cDNA $_\beta$ (ref. 20) eluted from the agarose gel (see above) was ethanol precipitated using 20 μ g ml⁻¹ Dextran (Sigma) as a carrier. After pelleting, the cDNA was resuspended and digested with 100 units μ g⁻¹ of *Hae*III restriction endonuclease in 10 mM Tris HCl, pH 7.6, 10 mM MgCl₂, 1 mM dithiothreitol for 4 h at 37 °C. The digested sample was directly loaded on a 7.5% polyacrylamide gel in E buffer and the separated bands located and recovered as described above. All the probes used for the hybridisation were further purified from contaminating α sequences by annealing to excess $\alpha\gamma$ mRNA and HAP chromatography⁵. DNAs were mixed with increasing amounts of *Hae*III H 1 (ref. 21) cDNA $_\beta$ fragment (*b*), or 3' end cDNA $_\beta$ probe (*c*), and hybridised as above for 5,000 min. A background S₁ nuclease resistance of 0.4% was subtracted.

Fig. 2 Cleavage pattern of δ and β globin genes with different restriction enzymes. High molecular weight DNA was prepared according to Britten *et al.*³⁰ from normal human placenta or from purified white cell nuclei³¹ of the $\delta^\circ\beta^\circ$ homozygous patient. DNA (30 μ g) was digested with the indicated restriction enzymes, denatured with alkali^{32,33} and electrophoresed in 0.8% agarose gel in E buffer¹⁶. DNA transfer on to nitrocellulose filters and hybridisation at 65 °C in 2 $\times$ SSC was according to Jeffreys and Flavell^{32,33} using nick-translated³² pHBG1 plasmid as a radioactive probe (specific activity 50–300 $\times$ 10⁶ c.p.m. μ g⁻¹). Filter washing was carried out in 0.1 $\times$ SSC (*a*) at 65 °C for 6 h with vigorous shaking. This washing procedure seems to be more stringent than that used by Flavell *et al.*^{29,32,33} at the same salt concentration, as shown by the faintness of δ bands in 0.1 $\times$ SSC (*a*) and the absence of γ bands even at 0.3 $\times$ SSC (*b*).

with mRNA $_{\alpha\gamma}$ and HAP fractionation⁵. Figure 1*b* shows that this 5'-end fragment does not hybridise to HPFH DNA (as expected), whereas it does hybridise to a comparable extent to both Lepore and $\delta^\circ\beta^\circ$ DNA (30% and 40%, respectively, of the normal). As the non- α chain of this case of Hb Lepore is a Boston type (in which a change-over from the δ -like sequence to the β -like sequence occurs between amino acids 87 and 116 (refs 25, 26)), this result demonstrates that this portion of the cDNA $_\beta$ can cross-hybridise to the corresponding δ sequence.

A 3'-end probe was obtained by eluting from an agarose gel a partial transcript (of approximately 200–250 nucleotides) obtained by reverse transcription of α -thalassaemic mRNA. In agreement with Efstradiatis (see ref. 27, and results not shown), we find that these fragments are incomplete oligo(dT)-containing products initiated at the 3'-poly(A) tail of the template and terminated at defined internal points. In contrast to the results obtained with the 5'-end probe, this fragment (further purified as above by HAP chromatography) does not hybridise with $\delta^\circ\beta^\circ$ DNA; the same was obtained with HPFH DNA, whereas the Lepore DNA hybridised to approximately 40–50% of normal (Fig. 2*c*), in agreement with the expected absence of the 3' end of the δ gene (which in these conditions seems to cross-hybridise efficiently to the probe used).

Two different schemes can fit our data; first, that the 5' end of the β -globin gene is retained in $\delta^\circ\beta^\circ$ thalassaemia, whereas the whole of the δ gene and the 3' end of the β -globin gene are missing:

alternatively, only the 5' δ -globin fragment would be present:

To distinguish between these two possibilities, we carried out mapping experiments using as a probe nick-translated radioactive pHBG1 plasmid containing human β -globin sequences²⁸.

As shown in Fig. 2, on digestion with *Eco*RI, $\delta^\circ\beta^\circ$ DNA shows, instead of the three main bands of 6.5, 4 and 2.3 kilobases present in normal DNA²⁹, a single band running slightly faster than the 4-kilobase β fragment; this result agrees with that reported by Mears *et al.* in a different patient³⁴. Double digestion with *Bam*HI and *Bgl*II results in a single 3.3-kilobase fragment in the $\delta^\circ\beta^\circ$ DNA; in normal DNA this fragment can originate both from the 3' end β gene and from the 5'-end δ gene. Thus, two alternative schemes can be proposed: the first

Fig. 3 Physical maps of δ and β DNA region in normal (a) and thalassaemic (b) DNA. Normal map is from Flavell *et al.*³⁰, $\delta^{\circ}\beta^{\circ}$ map was deduced from the digests reported in Table 1. B, *Bam*HI; Bg, *Bgl*II; E, *Eco*RI; P, *Pst*I; X, *Xba*I. The position of the *Pst*I site 5' to the δ gene in $\delta^{\circ}\beta^{\circ}$ patient is based mainly on its location in normal DNA and indirectly deduced from the persistence of the flanking *Eco*RI and *Xba*I sites.

implies the deletion of the β -globin gene and possibly part of the δ gene; the second requires deletion of the δ gene and the 5' end of the β -globin gene. The demonstration of the normal 1.3-kilobase *Bam*HI + *Eco*RI fragment (Fig. 2 and Table 1) and the 0.7-kilobase *Bam*HI + *Xba*I fragment (Table 1) in the $\delta^{\circ}\beta^{\circ}$ DNA confirms the validity of the first scheme. The experiment shown in Fig. 2 was carried out in highly stringent conditions (see Fig. 2 legend), a fact that explains the faintness of the δ bands. As expected, the use of less stringent washing conditions (Fig. 2b) results in a striking increase in the intensity of these bands (nevertheless, these conditions are stringent enough to prevent the cross-hybridisation of γ genes to the β probe, as confirmed by control experiments with HPFH DNA, not shown).

From the liquid hybridisation and restriction mapping experiments, we conclude that: (1) a 5'-end fragment is retained in $\delta^{\circ}\beta^{\circ}$ thalassaemia (Fig. 1b) which can be identified as the 5' end of the δ gene (Fig. 2 and Table 1); (2) no δ or β 3'-end fragments are retained in $\delta^{\circ}\beta^{\circ}$ DNA, as shown by liquid hybridisation methods (Fig. 1c), by the absence of the normal 4-kilobase fragment in the *Eco*RI + *Bam*HI double digest, and by the disappearance of the 2.3-kilobase δ fragment expected if the *Eco*RI site present in the δ gene-coding region were retained; (3) from the data in Table 1 we have constructed the physical map (Fig. 3) of the $\delta\beta$ -globin region in this $\delta^{\circ}\beta^{\circ}$ thalassaemic DNA. It is clear that the deletion removes a large DNA fragment beyond the δ intragenic *Bam*HI site, extending past the first *Eco*RI site, on the 3' side of the β -globin gene region: in fact, the relative positions of the *Pst*I, *Xba*I, *Bgl*II and *Eco*RI sites in this region do not correspond to the normal ones.

Genetic data based on the analysis of the non- α chain of Hb Kenya (a $\gamma\beta$ fusion product^{35,36}) and Hb Lepore ($\delta\beta$ fusion product) indicate that the most likely arrangement of the non- α genes on the chromosome is $\gamma^{\circ}\gamma^{\circ}\delta^{\circ}\beta^{\circ}$. Because Hb Kenya mutation is associated with high levels of HbF in adult life, whereas usually the Hb Lepore is not, a 'deletion hypothesis' (refs 37, 38) has been proposed to explain the molecular basis of HPFH. According to this model, the deletion in HPFH involves an area of the $\gamma\delta\beta$ -gene complex (probably located to the left of the δ gene; Y area of Huisman *et al.*³⁷) which is crucial to the post-natal suppression of γ -chain production; removal of this DNA segment allows the combined expression of γ genes, although not to the extent that they function in fetal life.

Our results only partially agree with this model, as a significant de-repression of γ genes occurs even in the presence of an intact 5'-end region of the δ gene. Thus, the structural δ -gene sequences and/or the insert might be part of the postu-

lated regulatory area controlling γ -gene expression. On the other hand, a larger deletion, involving an additional region including the 5' end of the δ gene, results in the HPFH picture. Establishment of the exact DNA region involved in determining the difference between the HPFH and $\delta^{\circ}\beta^{\circ}$ thalassaemia picture, will require mapping studies of non-structural gene areas at the 5' end of the δ gene in additional patients (see Orkin *et al.*²³). So far, our data are consistent with the hypothesis of Huisman *et al.*³⁷ that a continuum of molecular lesions might exist between two extremes: the HPFH syndrome with maximum de-repression of γ -chain synthesis and deletions extending from the β -globin gene to the γ gene; and the $\delta^{\circ}\beta^{\circ}$ thalassaemia with minor de-repression of the γ -globin genes and a more limited gene deletion.

We thank Drs Peter Little and Bob Williamson for the gift of pHSG1 and pHYG1 plasmids, Professor L. Luzzatto for stimulating the collaboration between Kumasi and Milano Universities, Drs N. Cattaneo and A. Rossi for providing HbH blood samples, and Drs G. Lanyon and I. Pragnell for sending HPFH DNA. This work was partially supported by the CNR grant CT 7701451.04 to E.P., and a grant from Fondazione Anna Villa Rusconi, Varese.

Common regulatory mechanism of expression and conjugative ability of a tetracycline resistance plasmid in *Bacteroides fragilis*

RESISTANCE to various antibiotics is common in the anaerobic gut bacterium *Bacteroides fragilis*. A transferable plasmid coding for resistance to antibiotics of the lincosamide/macrolide/synergistin groups has been found^{1,2} and transfer is most probably a conjugative process. This supports the observation of the recent emergence of resistance to antibiotics in these groups and its rapid spread in certain areas (ref. 3 and our unpublished data). However, in the case of tetracycline resistance the limited genetic and physical data were at variance with the epidemiological data. Although tetracycline resistance is common in *B. fragilis*⁴ (at present 60% of strains isolated in the USA⁵ and 30% of those isolated in France (our unpublished results) are resistant) intraspecies transfer of tetracycline resistance could not be demonstrated⁶. We report here that transfer of tetracycline resistance between *B. fragilis* strains is easily achieved if the donor bacteria are grown in the presence of tetracycline before mating. This suggests that tetracycline resistance is borne on a transferable plasmid whose conjugative transfer requires activation of the tetracycline resistance gene. This is supported by our finding that the transfer of tetracycline resistance is either inducible or constitutive, depending on whether tetracycline resistance itself is respectively inducible by tetracycline or constitutive.

At first we failed to transfer Tc resistance from *B. fragilis* strain 92 to a sensitive plasmid-free *B. fragilis* strain (638 rfm); using the same recipient we occasionally succeeded in transferring Tc resistance from a *B. distasonis* donor strain (BEN) at very low frequency¹. Nevertheless, with both donor strains, erythromycin-clindamycin (Em-Cl) resistance was easily shown to be transferable. The plasmid character of resistance to the

macrolides, the lincosamines, and to the synergistins was obvious because they were curable *en bloc* and were easy to characterise in strain 92 and transipients as DNA molecules of molecular weight between 27,000 (ref. 2) and 28,000 (our unpublished results). In similar experiments we failed to eliminate the Tc resistance¹ but the extrachromosomal localisation of Tc resistance was shown in an Em-Cl cured derivative of strain 92 and in Tc transipients (plasmid of 17,000 molecular weight).

It seemed possible that the rapid spread of Tc resistance in *B. fragilis* could be due to a plasmid whose transfer requires certain conditions present in its usual human or animal habitat (the intestine), but not in the normal experimental situation. Among the possible factors 'necessary' for this transfer, a good candidate was tetracycline itself which is widely used in therapy and in animal foods.

In strain 92, tetracycline resistance is inducible by tetracycline if the bacteria are exposed to the antibiotic for 1 h or more (Fig. 1); this strain is said to be Tc^R. The mechanism of plasmid-mediated Tc resistance is not known in *B. fragilis*. But we can reasonably assume that it is under negative regulatory control, as is inducible Tc resistance in facultative anaerobic bacteria⁷.

When strain 92 was cultivated for several generations in the presence of subinhibitory concentrations of tetracycline and then immediately mated with the recipient, Tc transipients were obtained. Results of a typical experiment are given in Table 1, and similar results were obtained in other serial subculture experiments. The number of Tc transipients recovered increased during these initial subcultures to 10⁵-10⁷ ml⁻¹ (Table 1, column 3), and at the same time the number of Em-Cl transipients was relatively stable, or decreased by spontaneous curing of the Em-Cl plasmid. The ratios of Tc^R transipients to Em^R transipients are indicated in Table 1 as an approximate measure of Tc transfer efficiency.

When the donor strain was in contact with tetracycline for 15 generations or less, its ability to transfer Tc resistance was strictly inducible (Tra_i), as it disappeared when the Tc-induced cultures were serially subcultured in the absence of tetracycline for >120 generations (de-induction). The Tc resistance of these de-induced cultures remained inducible (Tc^R), as in the original strain. In contrast to these results, data from Table 1 show that after more generations (>20) of the donor strain in the presence of tetracycline, its ability to transfer Tc resistance was maintained after de-induction; the transfer ability appeared to be constitutive (Tra_c). Concomitantly, the Tc resistance itself turned out to be constitutive (Tc^R). After a greater number of

Table 1 Inducibility against constitutivity of Tc transferability and Tc resistance in *B. fragilis* strain 92

92-Tc ₂₀	40	+	+	—	i and c	i and c
92-Tc ₂₅	40	+	+	—	c	c

* The donor strain was inoculated at 4 × 10⁷ bacteria ml⁻¹ in TYG broth¹ in the presence of variable concentrations of tetracycline. Subcultures were similarly made daily from the higher non-inhibitory Tc concentration. In these conditions each subculture is equivalent to five generations. After 5, 10... generations in the presence of Tc, strain 92 is designated as 92-Tc₅, 92-Tc₁₀ and so on.

† Conjugative ability was tested after each subculture in the presence of Tc, by mating the donor with *B. fragilis* 638 rfm according to ref. 1; 0.05 ml of each strain were mixed onto TYG plates of 5 cm diameter. After an overnight incubation the culture was scraped, suspended in 2 ml of TYG and various dilutions of the suspension spread onto agar plates supplemented with rifampicin (Rfm) at 25 μg ml⁻¹ and either tetracycline (Tc) at 2 μg ml⁻¹ or erythromycin (Em) at 10 μg ml⁻¹. The numbers of transipients per ml of this suspension are indicated in column 3. Isolation and characterisation of transipients, and conditions of growth were as in ref. 1.

‡ After each subculture in the presence of Tc, the culture was de-induced by growth without Tc for at least 120 generations and tested for its transferability as before.

§ After de-induction, the cultures were tested for inducibility (i) versus constitutivity (c) of Tc resistance using the conditions in Fig. 1, except that the induction time was routinely 18.

serial subcultures (between 40 and 100 generations) in the presence of tetracycline, identical results were obtained, but the minimal inhibitory concentrations (MIC) of Tc for the donor were significantly higher ($100 \mu\text{g ml}^{-1}$) than initially ($16 \mu\text{g ml}^{-1}$), in contrast to identical values during the initial serial subcultures (MIC Tc, $20\text{--}40 \mu\text{g ml}^{-1}$).

In the experiment described in Table 1, the de-induced donor 92-Tc₂₀ which was at first phenotypically Tra₊ turned out to be a mixture of Tc^R and Tc^S clones; when both clones were rechecked for ability to transfer Tc resistance, they were found to be Tra₊ and Tra₋ respectively.

The number of generations in the presence of tetracycline required to obtain constitutive Tc resistance and Tc transfer varied from one serial subculture experiment to another, but the phenomenon was experimentally reproducible between the 10th and 25th generations.

The fact that Tc transfer appeared even after a few generations (5–25) in the presence of tetracycline without significant modification of the MIC of the donor seems to suggest a modification of the conjugative ability itself, rather than quicker or more efficient Tc^R expression in transipients. Two findings support this view. (1) In the mating of strain 92 (without any previous contact with Tc) and of the recipient strain 638 rfm, no Tc transipients were obtained even when the Tc concentration was lowered in the selective plates to $0.2 \mu\text{g ml}^{-1}$ instead of $2 \mu\text{g ml}^{-1}$ as used in all experiments previously reported (MIC Tc of the recipient strain, $0.064 \mu\text{g ml}^{-1}$). (2) In a similar mating using as donor a Tra₊ Tc^R strain obtained by 20 serial subcultures at a sub-inhibitory concentration of tetracycline (MIC Tc, $100 \mu\text{g ml}^{-1}$) the same number of transipients was obtained by using for the selection different concentrations of tetracycline (Table 2).

We verified that the Tc plasmid transfer was specifically induced by tetracycline or minocycline, but not by erythromycin. The Em-CI plasmid is not required for Tc plasmid transfer, because identical results were obtained with strain 92-1 which is a derivative, cured of its Em-CI plasmid¹.

Physical analysis of Tc transipients and of a Tra₊ Tc^R derivative from strain 92 shows that these strains harbour a plasmid of molecular weight 17,000 as does the wild type strain; consequently plasmid amplification can be ruled out as a possible mechanism for the newly acquired properties.

Fig. 1 Induction of tetracycline resistance in *B. fragilis* strain 92. Cultures inoculated with early stationary cells (10^8 cells ml^{-1}) were grown in TYG broth¹ for 1 h without tetracycline (Tc) (a) or with $0.5 \mu\text{g ml}^{-1}$ of Tc (b). At this time (T_0) they were inoculated at 5×10^6 cells ml^{-1} in TYG broth without Tc (O) or with Tc at $5 \mu\text{g ml}^{-1}$ (x). Cultures were incubated at 34°C in anaerobic jars and the optical densities were measured at hourly intervals (Klett photocolormeter, filter no. 54).

Table 2 Mating of strain 92-Tc₁₀₀ and strain 638 rfm*

	Tc concentration in the selective plates ($\mu\text{g ml}^{-1}$)†		
	2	20	40
No. of transipients‡	3.2×10^3	3.0×10^3	2.1×10^3

* The donor strain had a MIC for Tc of $100 \mu\text{g ml}^{-1}$. Before mating it was de-induced by 150 generations in TYG broth in the absence of tetracycline. Other experimental conditions were as in Table 1.

† Selection was made onto TYG agar medium supplemented with rifampicin at $25 \mu\text{g ml}^{-1}$ and tetracycline at the indicated concentration.

‡ The number of transipients is expressed per ml of mating suspension (see Table 1)

Similar results were obtained with other clinical isolates of *B. fragilis*; in these strains, Tc resistance and transfer ability were shown to be inducible by tetracycline in the same experimental conditions. Similarly, when strain BEN of *B. distasonis*¹, also Tc^R, was used as a donor, a considerable increase ($>10^3$) in Tc^R transipients was regularly obtained when the strain was subcultured in the presence of tetracycline before mating. The phenotype Tra₊ can be attributed to this strain in spite of its very low Tc^R conjugative ability without Tc induction¹. In strain BEN it is probable that an Em-CI plasmid is co-transferred by Tc plasmid¹. The induction of transferability of Tc plasmid led to a parallel increase of co-transfer. Spontaneous Tra₊ Tc^R mutants were also obtained from strain BEN.

These results show that growth of a few generations of the Tc^R donor strain in the presence of tetracycline reversibly and specifically induces Tc conjugative ability. This suggests induction (or de-repression) of the conjugative ability of the Tc plasmid by tetracycline. At the same time tetracycline is likely to act as the inducer or de-repressor of a product required for expression of Tc resistance. This result is comparable to two reports from studies of metabolic plasmids: Nakasawa and Yokota⁸ showed stimulation of TOL plasmid transfer by *m*-toluate in *Pseudomonas putida*, and Petit *et al.*⁹ demonstrated a stimulatory effect of nopaline or octopine on Ti plasmid transfer in *Agrobacterium tumefaciens*. Our findings with an antibiotic resistance plasmid confirm the prediction of Petit *et al.*⁹ that RTF factors will exist with a conjugative ability inducible by the antibiotic whose resistance they are coding. The induction of plasmid transfer by induction of a gene carried on it appears therefore to be a widespread phenomenon in bacteria. Moreover, with *B. fragilis* strain 92, a greater number of generations grown in the presence of Tc led to Tc^R derivatives stably constitutive for transfer (Tra₊) (data not shown). These derivatives are probably spontaneous mutants selected by the antibiotic, whose mutation confers constitutivity for both Tc resistance and Tc^R conjugative ability. The mutation could be in a regulatory gene controlling both properties.

These results lead us to postulate for the Tc plasmids of *B. fragilis* a common regulatory mechanism for resistance and for conjugative ability. These results may help to explain the emergence of Tc^R strains in the intestinal flora during long-term tetracycline therapy. They emphasise the extreme danger of using tetracycline in animal foods or in therapy, unless strictly indicated.

Cytochrome c_2 sequence variation among the recognised species of purple nonsulphur photosynthetic bacteria

IN higher organisms, the nature and amount of amino acid sequence difference between homologous proteins from different species correlates well with what is known about the phylogeny of the organisms from morphological and palaeontological evidence¹⁻³. We are interested in the application of amino acid sequence information to the study of bacterial phylogeny, a subject that is not amenable to investigation by the classical methods because of the paucity of morphological features and the lack of a palaeontological record. We have, therefore, determined the amino acid sequences of the principal soluble cytochromes c of representatives of each recognised species of the Rhodospirillaceae, the nonsulphur purple photosynthetic bacteria. In contrast to higher organisms, there was no correlation between a species' cytochrome c amino acid sequence and its phylogenetic position.

The Rhodospirillaceae are the best studied group of phototrophic bacteria^{4,5}, and they have been divided into three genera containing a total of 12 species⁶ (Table 1). The properties of most of these species were found by the study of numerous separate isolates in pure culture. The different species (Table 1) vary widely in their physiology and morphology, and most seem to be definite taxonomic entities. Selected strains of each species have been grown in large quantities and contain high concentrations of a variety of photosynthetic pigments and electron transport proteins⁷, of which the relevant ones are shown in Table 1.

Rhodospirillum rubrum is the type species of the family which produces the well known cytochrome c_2 . Both the amino acid sequence⁸ and the three dimensional structure⁹ are known, and considerable similarity to mitochondrial cytochrome c has been recognised in both sequence and folding. Cytochromes c_2 function in photosynthetic electron transport^{10,11}. They may also function in some modes of non-photosynthetic metabolism, but this is not proved.

We have examined the major, soluble, low-spin c -type cytochromes from 11 other species of Rhodospirillaceae. Most of them produce a protein (or proteins) that resemble cytochrome c_2 and mitochondrial cytochromes c in sequence (Fig. 1). However, two of the species, *Rhodospirillum tenue* and *Rhodopseudomonas gelatinosa*, do not apparently produce any protein of this class but instead form a cytochrome¹² that resembles the small cytochrome c -551 of the denitrifying pseudomonads. The cytochromes c_2 from five of the species (Fig. 1*c-i*) have amino acid sequences resembling those of mitochondrial cytochromes c at least as closely as they do those of *R. rubrum* cytochrome c_2 . These sequences can be aligned with those of the mitochondrial proteins with good matching throughout¹³ (Fig. 1). The remaining four species (Fig. 1*j-o*) produce proteins that resemble *R. rubrum* cytochrome c_2 in that they have appreciably longer sequences than the others (116-124 residues), and to get good matching with the smaller cytochromes c_2 or with mitochondrial cytochromes c require at least three- and eight-residue insertions plus a single-residue deletion. Each of these four species produces sequences containing distinctive insertions and deletions. The cytochrome c -550 from the denitrifying bacterium *Paracoccus denitrificans*^{14,15} also belongs to this sequence group, and shows particular affinity to the *Rhodopseudomonas capsulata* sequence.

We have examined the proteins from two independent strains of *Rps capsulata* and *Rhodopseudomonas palustris*. The former proteins differ from each other in only two positions, while the latter differ in 12 positions. These differences are much smaller than those between any two different species except *Rhodospirillum molischianum* and *Rhodospirillum fulvum*.

*R. molischianum*¹⁶ and *R. fulvum* both produce two distinct soluble cytochromes c_2 . Despite earlier reports¹⁶, both isocytocromes are very similar in size. The sequences of both the *iso*-1-cytochrome c_2 and the *iso*-2-cytochrome c_2 of *R. fulvum* differ from the corresponding proteins of *R. molischianum* in 12 positions. *Rhodospirillum molischianum* and *R. fulvum* are taxonomically similar⁶, the main distinctions between them being cell width *p*-aminobenzoate requirement and ability to utilise benzoate.

The *iso*-1-cytochrome c_2 of both *R. molischianum* and *R. fulvum* lack the 'evolutionarily invariant' tryptophan residue at position 59 (Fig. 1), common to all natural mitochondrial cytochromes c so far examined and to the other cytochromes c_2 shown in Fig. 1. An unstable mutant form of yeast cytochrome c has been produced in which this tryptophan residue has been replaced¹⁷.

The *iso*-2-cytochromes c_2 of both *R. molischianum* and *R. fulvum* seem to contain a mixture of phenylalanine and tyrosine

Fig. 1 Amino acid sequences of Rhodospirillaceae cytochromes *c*₂ aligned with selected mitochondrial cytochrome *c* sequences. Residues are numbered from the horse (*a*) sequence. Underlined residues are referred to in this caption. In sequence *b* residue 86 is *ε*-*N*-trimethyl-lysine. In sequence *e* the evidence for the amide ascriptions among residues 87–90 is weak. In sequences *h* and *i* position 67 contains phenylalanine (about 30%) as well as the predominant tyrosine. In sequence *i* only the compositions of regions 32–36 and 93–97 are known. In sequence *k* there is conflicting evidence, some of which suggests that there is an additional glycine residue between residues 56 and 57. Sequence *o* is for *Rps capsulata* strain 2.3.1; in strain St Louis, residue 75 + 4 is leucine (not threonine) and residue 78 is threonine (not serine). Experimental evidence will be published elsewhere. The one-letter notation used is that recommended by the IUPAC-IUB Commission on biochemical nomenclature. A, alanine; C, cysteine; D, aspartic acid; E, glutamic acid; F, phenylalanine; G, glycine; H, histidine; I, isoleucine; K, lysine; M, methionine; N, asparagine, P, proline; Q, glutamine; R, arginine; S, serine; T, threonine; V, valine; W, tryptophan; Y, tyrosine.

at the position that corresponds to the highly conserved tyrosine-67 of mitochondrial cytochromes *c*. Such polymorphism is well established in higher organisms, where it can occur through population differences¹⁸, heterozygosity, or multiple genes^{19,20}. Only the last of these explanations can apply to the prokaryotes in the present instance. It is remarkable that this heterogeneity is present at the same site in the proteins of two organisms that have otherwise diverged appreciably.

Our results show that the deduction of phylogenetic information from the sequence of homologous bacterial proteins is not straightforward. Studies of the sequences of cytochromes *c*-551 from different *Pseudomonas* species^{21,22} have shown interspecific differences to be much larger than intraspecific differences. Sequence differences between similar species for these cytochromes *c*-551 are as large as those between mitochondrial cytochromes *c* of mammals and insects, although both classes of protein probably have similar redox functions. Our results for the Rhodospirillaceae emphasise this sequence variability more strongly. The predominant low-spin cytochromes *c* from these organisms fall into three distinct sequence classes whose distribution (Table 1) do not correlate with the genera into which the family has been divided on a morphological basis^{5,6}. Even within one of these sequence classes, the cytochrome *c* is more variable between different species of the bacterial family than it is across the whole range of eukaryotic mitochondria. It could be argued that this sequence heterogeneity in the Rhodospirillaceae is a consequence of the extreme age of the family, as organisms with a similar photosynthetic capability could have flourished in the Precambrian epoch before the appearance of oxygenic photosynthesis. Nevertheless, this theory does not predict the lack of correlation of sequence type with morphology nor the occurrence of the similarities observed between the cytochromes of species of Rhodospirillaceae and those of organisms with very different metabolic patterns, for example, *Rps capsulata* and *P. denitrificans*¹⁵, *Rhodopseudomonas viridis* and mitochondria¹³ (Fig. 1), or *R. tenue* and *Pseudomonas aeruginosa*¹².

Our observations are consistent with the hypothesis that bacterial evolution proceeds both by the assimilation of genes for single functions or for whole metabolic pathways from other organisms as well as by the gradual processes of mutation and selection. We have no information about the frequency of successful gene assimilation or about the timescale for protein evolution and speciation in bacteria. We have no evidence at all

to suggest that either a gene product (such as a cytochrome *c*) or an assemblage of genes (such as *Rhodospirillum rubrum*) should be stable through geological time.

These studies have been supported in part by grants to R.P.A. from the MRC and to M.D.K. from the NIH (GM-18528) and the NSF (BMS-75-13608). We thank G. W. Pettigrew for *R. photometricum* cytochrome *c*₂.

Anomalies in amino acid sequences of small cytochromes *c* and cytochromes *c'* from two species of purple photosynthetic bacteria

MOST species of the Rhodospirillaceae¹, the purple nonsulphur photosynthetic bacteria, produce large quantities of cytochrome *c*₂ (ref. 2), a protein which is similar in sequence to mitochondrial cytochrome *c*³. Many species also produce the high-spin haem protein cytochrome *c'* (ref. 2). Cytochromes *c'* have been identified in *Rhodospseudomonas gelatinosa* and in *Rhodospirillum tenue*, but in these organisms the predominant low-spin cytochromes *c* do not have properties similar to those found for cytochromes *c*₂ (ref. 2). We have now determined the amino acid sequences of the cytochromes *c'* and of the predominant low-spin cytochromes *c* from the two organisms (Fig. 1).

Comparison of these sequences with those of analogous cytochromes reveals some anomalies (Table 1). The sequences of the two low-spin cytochromes, *Rps gelatinosa* cytochrome *c*-551 and *R. tenue* cytochrome *c*-553 (Fig. 1a) markedly resemble the cytochromes *c*-551 of denitrifying pseudomonads⁴ and of *Azotobacter vinelandii*⁵. For alignment with the *Pseudomonas* and *Azotobacter* sequences, the *Rps gelatinosa* cytochrome requires the postulation of a three-residue insertion immediately after the methionine residue which is presumed to be the sixth iron ligand, while alignment of the *R. tenue* cytochrome requires the postulation of a five-residue insertion shortly before this methionine residue (Fig. 1a). The *R. tenue* cytochrome *c*-553 is particularly similar in sequence to the cytochrome *c*-551 of *Pseudomonas aeruginosa* (Fig. 1a), even in regions that are variable among the *Pseudomonas* species of known sequence^{4,5}.

The sequences of the cytochromes *c'* (Fig. 1b) can be aligned with each other if a one- and a three-residue deletion are postulated in the *Rps gelatinosa* sequence, and a single one-residue deletion is postulated in the *R. tenue* sequence. The sequences show 31% identity overall when so aligned, with poor matching between residues 16 and 50 (Fig. 1b). This compares with 37% identity for the cytochromes 'c-551' (Fig. 1a) and the

27% determined in another study⁶ for their high potential iron sulphur proteins (HiPIP) (Fig. 1c). The sequences of three other cytochromes *c'* are already known, those of an *Alcaligenes* species⁷, *Rhodospirillum rubrum*⁸ and *Chromatium vinosum*⁹. If a two-residue insertion is postulated, the *Rps gelatinosa* cytochrome *c'* matches well with the *Alcaligenes* protein (48% identity) and if a one-residue insertion is postulated, the *R. tenue* cytochrome *c'* matches well with the *C. vinosum* protein (47% identity). In both these cases, good matching extends throughout the sequences (Fig. 1b). The sequence of the cytochrome *c'* from *R. rubrum* is known⁸ and those from *R. molischianum*, *R. fulvum*, *Rps capsulata* and *Rps palustris* are being investigated. None of these proteins resemble the *R. tenue* protein as closely as that protein resembles the *C. vinosum* cytochrome *c'*; neither do any of them resemble the *Rps gelatinosa* protein as closely as that protein resembles the *Alcaligenes* cytochrome *c'* (R.P.A., T.E.M., R. G. Bartsch and M.D.K., unpublished results). The cytochromes 'c-551' and the cytochromes *c'* of *Rps gelatinosa* and *R. tenue* all seem to be anomalously closer in sequence to proteins from organisms of other families, including non-photosynthetic ones, than they are to proteins of other members of the Rhodospirillaceae. *Rps gelatinosa* and the strain of *Alcaligenes* are very different both physiologically and in electron transport protein complement¹⁰. The pattern of similarity observed for the cytochromes *c'* does not apply to the HiPIPs, as the *R. tenue* HiPIP is more different to that from *C. vinosum* than to any of the others of known sequence⁷. *C. vinosum* has been reported to contain a cytochrome *c*-551 (ref. 11), but the amount present is small and nothing is yet known about its structure. Pfennig¹² has recently discussed the relationship between the Chromatiaceae and the Rhodospirillaceae. A reassessment of the evidence of sulphur metabolism, and a consideration of the genus *Ectothiorhodospira* has lessened the distinction between these families; some similarity between their electron transport proteins can now be expected.

To detect evolutionary anomalies, it has been proposed (for example, by Wilson *et al.*¹³) that the amino acid sequences of several different gene products from a set of organisms should be compared, so that evolutionary trees might be constructed and tested for congruence. Although the comparison of three sets of proteins from three different species does not provide sufficient data on which to base firm conclusions, phylogenetic trees constructed from the results in Table 1 could never be interpreted as congruent, nor would they have any predictive value.

Fig. 1 Amino acid sequences of a, cytochromes 'c-551'; b, cytochromes *c'*; c, high potential iron sulphur proteins (HiPIP)⁷ from *Rhodospseudomonas gelatinosa* strain 2.2.1 (= ATCC 17011) and from *Rhodospirillum tenue* strain no. 3761. The sequences are shown aligned with other proteins of the same class and known sequence. In b, vertical lines mark identical residues in adjoining sequences. The evidence for the sequence of the underlined residues in *R. tenue* cytochrome *c'* (AANT) is weak. Experimental evidence for the sequences will be published elsewhere. The one-letter notation used is that recommended by the IUPAC-IUB Commission on biochemical nomenclature. A, alanine; C, cysteine; D, aspartic acid; E, glutamic acid; F, phenylalanine; G, glycine; H, histidine; I, isoleucine; K, lysine; L, leucine; M, methionine; N, asparagine; P, proline; Q, glutamine; R, arginine; S, serine; T, threonine; V, valine; W, tryptophan; Y, tyrosine.

Table 1 Similarity matrices for amino acid sequences of cytochromes 'c-551', cytochromes c' and high potential iron sulphur proteins (HiPIP)⁶

Cytochromes 'c-551'			Cytochromes c'		
<i>Rhodospirillum tenue</i>			<i>Rhodospirillum tenue</i>		
37	<i>Rhodopseudomonas gelatinosa</i>		31	<i>Rhodopseudomonas</i>	
56	39	<i>Pseudomonas aeruginosa</i>		<i>gelatinosa</i>	
45	38	60 <i>Azotobacter</i>	47	28	<i>Chromatium vinosum</i>
		<i>vinelandii</i>	29	48	24 <i>Alcaligenes</i> sp.
HiPIP ⁶					
<i>Rhodospirillum tenue</i>					
27	<i>Rhodopseudomonas gelatinosa</i>				
21	37	<i>Chromatium vinosum</i>			

Values shown are matches per 100 residues when the sequences are aligned as in Fig. 1.

Noncongruence of evolutionary trees for *Desulfovibrio* and *Clostridium* ferredoxin and rubredoxin has already been observed¹⁴.

Noncongruence of protein evolutionary trees could be caused by several mechanisms. In higher organisms several anomalies have been explained by the realisation that 'paralogous' proteins had been compared¹⁵. Noncongruence could also be caused if the rate of change of the proteins in separate branches were very different. If functional requirements severely limit the possibility of further change in a protein, the possibility of evolutionary convergence would be increased and would cause further distortion. Nevertheless the simplest (if most difficult to prove) explanation for all the anomalies described is that the proteins concerned have reached some of the organisms by processes of interspecific gene transfer.

These studies have been supported in part by grants to M.D.K. from the NSF (BMS-75-13608) and the NIH (GM-18528) and to R.P.A. from the MRC.

Processing of small subunit precursor of ribulose biphosphate carboxylase and its assembly into whole enzyme are stromal events

CHLOROPLAST development requires the activities of both nuclear and chloroplast genetic systems, but the precise contribution of each and the mechanism by which they interact are not understood. A prime goal is to determine the site of synthesis of each chloroplast polypeptide. Studies with isolated subcellular systems, as well as inhibitor experiments with intact cells, have established that many chloroplast polypeptides are made by cytoplasmic ribosomes¹. Such polypeptides include subunits of both thylakoid and stromal multi-subunit proteins. These observations raise two questions: how do these polypeptides traverse the chloroplast envelope, and where are they assembled into whole functional proteins? The small subunit of the chloroplast enzyme ribulose biphosphate carboxylase is made in the cytoplasm as a higher molecular weight polypeptide precursor². We report here that the cleavage of this precursor and the assembly of the small subunit into whole ribulose biphosphate carboxylase molecules takes place in the chloroplast stroma.

Isolated pea chloroplasts synthesise as the major soluble product the large subunit of ribulose biphosphate carboxylase/oxygenase, the key enzyme in photosynthesis and photorespiration³. The carboxylase enzyme (RBPCase) is an oligomer of 16 subunits. Besides eight large catalytic subunits, the whole enzyme contains eight small subunits (molecular weight 14,000) of unknown function, which are encoded in the nuclear genome⁴. We have shown that the small subunit is synthesised as a precursor of higher molecular weight (20,000) when poly(A)-containing RNA from pea leaf cytoplasmic ribosomes is translated by a heterologous protein-synthesising system^{2,5}. This precursor enters intact isolated chloroplasts with processing to the final size. This uptake and processing does not require concomitant protein synthesis, and thus differs from the signal mechanism advanced to explain the transport of polypeptides across the endoplasmic reticulum⁶. We have suggested an envelope carrier mechanism in which the small subunit precursor is released from cytoplasmic ribosomes and interacts through some aspects of its tertiary structure with a specific binding site in the chloroplast envelope^{2,3}. Unlike known signal sequences, the extra amino acid sequence present in the precursor was postulated to be charged, and its removal by an envelope protease was suggested to trigger a conformational change leading to the transport of the small subunit across the envelope. However, attempts to detect processing activity in preparations of pea chloroplast envelopes purified by the method of Joy and Ellis⁷ have been unsuccessful; instead we find the processing activity to be stromal⁸.

Small subunit precursor (P20) was synthesised by programming a wheat-germ protein-synthesising system with poly (A)-containing RNA from polysomes isolated from etiolated shoots of *Pisum sativum* greened for 48 h (ref. 2). After incubation for 60 min with ³⁵S-methionine the wheat-germ extract was centrifuged at 180,000g for 60 min to remove ribosomes and ribosome-bound labelled polypeptides. The supernatant solution contained P20 as the most heavily labelled polypeptide. Aliquots of this solution were incubated with fractions prepared from intact chloroplasts. Table 1 shows that the processing activity is present in both intact chloroplasts purified on silica-sol gradients, and in stromal extracts prepared from intact chloroplasts. In contrast to previous results², the activity in stromal extracts is not sedimented by centrifugation at 180,000g for 3 h; this treatment sediments both chloroplast ribosomes and whole RBPCase molecules. This soluble stromal nature of the processing activity has been observed in at least 10 separate

Fig. 1 Time course of processing of P20 to small subunit. Wheat-germ products and 3,200-g stromal supernatant fractions were prepared as in Table 1. Samples (10 μ l) of wheat-germ supernatant were incubated with 40- μ l samples of stroma for various times at 27 °C, and then boiled for 2 min in polyacrylamide gel loading buffer². Each incubation mixture contained the equivalent of 5.7 μ g chlorophyll and TCA-insoluble radioactivity equal to 2.5×10^5 c.p.m. Autoradiography and the quantification of the processing activity were as described in Table 1. The results presented are those obtained by counting the radioactivity in the P20 and small subunit bands of the polyacrylamide gel. *a*, Increase in radioactivity in small subunit over that present at zero time; *b*, decrease in radioactivity in P20 below that present at zero time.

experiments carried out independently by two workers. The failure of previous experiments to show that the processing activity is soluble may indicate a loose association of the processing activity with the inner membrane of the chloroplast envelope. The small subunit precursor from *Chlamydomonas* is also processed to the small subunit by a soluble enzyme⁹, but in that case it was not possible to show that the activity was located in the stroma because intact chloroplasts cannot be isolated from this alga.

Loss of label from P20 is not invariably associated with the appearance of label in the small subunit, as we have previously assumed. Membrane preparations often cause a decrease in P20 label, but this loss is never accompanied by an increase in small subunit label (Table 1) or other polypeptide. No other polypeptide synthesised by the wheat-germ system shows a decrease in label after incubation with any chloroplast fraction, suggesting that nonspecific proteolysis is absent. The time course of processing by stromal extracts shows that more label is lost from P20 than appears in the small subunit (Fig. 1). This observation establishes that the sequence removed during processing contains at least one methionine residue. If this methionine residue is at the N terminus, its removal by an N-terminal peptidase would account for the activity seen in the membrane preparations. Such N-terminal peptidase activity may also occur in the stromal fractions, but this is impossible to establish until specific inhibitors of processing are available.

The soluble nature of the P20 processing activity raises the question as to how it functions in the transport of the precursor through the chloroplast envelope. One possibility is that the precursor interacts with the envelope in such a way that the

sequence to be removed becomes accessible from the stromal side. Removal of the sequence may be the event which triggers the release of small subunit into the stromal compartment. A critical test of this idea would be to determine whether removal of the extra sequence by purified processing enzyme affects the ability of intact chloroplasts to take up the molecule.

An additional or even alternative role for processing may be in the assembly of whole RBPCase molecules. Analysis on

Table 1 Subcellular location of small subunit precursor processing activity

Fraction tested	% Decrease in label in small subunit precursor (P20)	% Increase in label in small subunit
Buffer	0	0
Washed chloroplasts	41	75
Purified intact chloroplasts	31	50
Lysed chloroplasts	33	45

Stroma 180,000g 1 h	41	47
Stroma 180,000g 3 h	40	62
Thylakoids	21	0
Envelopes	35	0

Poly(A)-containing RNA was prepared from pea leaf polysomes and translated in a wheat-germ protein-synthesising system as before², except that the final concentrations of KCl and MgCl₂ were 90 mM and 2 mM, respectively. After incubation, the wheat-germ extract was centrifuged at 180,000g for 60 min at 4 °C to sediment ribosomes and ribosome-bound polypeptides. This treatment sediments about 60% of the trichloroacetic acid (TCA)-insoluble radioactivity, leaving the small subunit precursor in the supernatant as the most heavily labelled polypeptide. During the preparation of the wheat-germ products chloroplasts were isolated from 10-d-old pea leaves as described previously³. These chloroplasts were washed once in isolation medium, and resuspended in intact plastid buffer prepared by mixing equal volumes of 10 mM Tris-HCl, pH 7.6 and 50 mM HEPES-KOH, 220 mM KCl, 6 mM MgCl₂, 20 mM dithiothreitol (DTT), pH 7.6. This preparation is referred to as washed chloroplasts, and consists of about 60% intact chloroplasts as judged by phase-contrast microscopy. Lysed chloroplasts were prepared by resuspending a pellet of washed chloroplasts in 10 mM Tris-HCl, pH 7.6, leaving it on ice for 5 min, and then adding an equal volume of 50 mM HEPES-KOH, 220 mM KCl, 6 mM MgCl₂, 20 mM DTT, pH 7.6. A sample of lysed chloroplasts was centrifuged at 3,200g for 5 min to obtain a stromal supernatant and a thylakoid pellet. The latter was washed once, and resuspended in an equal volume of intact plastid buffer. Samples of stroma were centrifuged further at 180,000g for 1 and 3 h at 4 °C while other preparations remained on ice. Intact chloroplasts were purified on gradients of Ludox AM silica sol¹² from a preparation of washed chloroplasts. Purified envelopes were prepared from washed chloroplasts by the method of Joy and Ellis⁷. For the measurement of processing activity, samples (10 μ l) of wheat-germ supernatant containing TCA-insoluble radioactivity equal to 2×10^5 c.p.m. were incubated with 40 μ l of chloroplast preparation, or fractions therefrom, for 60 min at 27 °C. Chlorophyll was measured by the procedure of Arnon¹³; each incubation contained the equivalent of 6 μ g chlorophyll, except that the purified chloroplast envelope incubation mixtures contained envelopes equivalent to 990 μ g chlorophyll. After incubation, samples were prepared for polyacrylamide gel electrophoresis and analysed as before². Gels were autoradiographed with Kodirex X-ray film for 100 h. Processing activity was measured quantitatively by two methods. Autoradiographs were scanned in a Joyce-Loebl densitometer, and the peak heights of the P20 and small subunit bands were measured for incubated and non-incubated samples. The change in peak height of each band due to the incubation was calculated as a percentage. In the other method the dried polyacrylamide gels were rehydrated, and the P20 and small subunit bands were excised. The gel pieces were dissolved in 0.2 ml H₂O₂ (100 volumes) at 50 °C overnight, and the radioactivity in each was counted in 4 ml Triton-toluene scintillant (0.4% (w/v) PPO, 0.005% (w/v) POPOP, 33% (v/v) Triton X-100 in toluene). The results presented were obtained by the first method and agree closely with those obtained by the second method. The percentage increase in small subunit label is not correlated with the percentage decrease in P20 label; this is because both the P20 and small subunit regions of the gel are contaminated with other products of the wheat-germ system in both the presence and absence of processing.

Fig. 2 Assembly of small subunit into whole RBPCase molecules. *a*, Separation of whole RBPCase molecules by transverse gradient non-denaturing gel electrophoresis. Wheat-germ products and a 3,200g stromal supernatant were prepared as in Table 1. Wheat-germ supernatant (50 μ l) containing 1.25×10^6 c.p.m. of TCA-insoluble radioactivity was incubated with 200 μ l of stromal extract, equivalent to 28.8 μ g chlorophyll, for 60 min at 27 °C. A control incubation mixture consisted of 50 μ l wheat-germ supernatant plus 200 μ l intact plastid buffer. After incubation, samples were brought to 300 μ l with a solution of sucrose and 2-mercaptoethanol with final concentrations of 10% (w/v) and 1.66% (v/v) respectively, for analysis by non-denaturing polyacrylamide gel electrophoresis. The gel system is based on that of Blair and Ellis³. A slab gel (17 $\times$ 17 cm) was cast with a linear gradient of 5–10% (w/v) acrylamide and 0.1–0.2% (w/v) bisacrylamide, stabilised with 0.2% (w/v) linear polyacrylamide. Once polymerised, the gel was turned through 90°, and a 5% (w/v) acrylamide, 0.1% (w/v) bisacrylamide slot former was cast along one edge of the gradient gel. The gel was pre-electrophoresed for 3.5 h at 30 mA. Samples of incubation mixture containing 2×10^5 c.p.m. TCA-insoluble radioactivity were loaded onto all the slots. Electrophoresis was for 18 h at 27 mA after which the gel was stained with Coomassie brilliant blue R and destained². The photograph shows the stained gel. RBPCase is the most heavily stained band, and is marked with an arrow at the 5% end of the gel. Other, minor bands, change their mobility relative to RBPCase according to the gel concentration. Autoradiography for 100 h shows radioactivity co-migrating with the stained bands of RBPCase, but not at corresponding positions in tracks lacking stromal extract (not shown). *b*, Identification of labelled small subunit in whole RBPCase molecules. The transverse gradient non-denaturing polyacrylamide gel shown in (*a*) was rehydrated, and each RBPCase region was excised. Gel pieces were equilibrated twice with 5 ml of 62 mM Tris-HCl, 2% (w/v) SDS, 0.5% (v/v) 2-mercaptoethanol pH 6.8 for 15 min each, and then affixed to the top of an SDS slab gel with 1% (w/v) Agarose, 0.2% (w/v) SDS, 62 mM Tris-HCl, pH 6.8. Electrophoresis was as previously described². The photograph shows an autoradiograph of the SDS gel in the small subunit region; the arrow marks the small subunit marker. The autoradiograph shows that radioactivity co-migrating with small subunit is present in RBPCase molecules excised from across the entire gradient of the non-denaturing gel. Other radioactive polypeptides migrate above and below the small subunit. However, these polypeptides vary in distribution across the gradient, indicating that they do not co-migrate with RBPCase at all gel concentrations. Control incubations lacking stromal extract contain no radioactivity in the small subunit region (not shown).

non-denaturing gels shows that the large subunit of RBPCase synthesised by isolated pea chloroplasts does not enter pre-existing RBPCase molecules³, but accumulates as an aggregate¹. This observation has been interpreted as indicating that isolated pea chloroplasts lack a pool of small subunits³. It follows that supplying P20 to pea chloroplast fractions may result in the assembly of whole RBPCase molecules. When wheat-germ incubation mixture containing labelled P20 is incubated with a stromal extract, labelled small subunit co-migrates with whole RBPCase molecules over a wide range of polyacrylamide gel concentrations when electrophoresed in non-denaturing conditions (Fig. 2). Co-migration in such conditions is a good test for identity¹⁰. Control experiments where stromal extracts were omitted from the incubation show no label migrating with whole RBPCase molecules. These observations establish that the assembly of small subunit into RBPCase occurs in the chloroplast stroma as previously proposed², and not in the cytoplasmic compartment. Chua and Schmidt¹¹ have reported the processing of P20 and assembly of small subunit into RBPCase in intact pea and spinach chloroplasts, but the stromal location of the processing and assembly process was not established. Whether processing is an integral part of the assembly mechanism, or merely provides small subunit for that mechanism, can be resolved when the processing activity has been purified.

Sites of inhibition of *in vitro* DNA synthesis in carcinogen- and UV-treated Φ X174 DNA

THE availability of DNA molecules of known sequence and rapid methods for the determination of the sequence of particular DNA fragments^{1–3} make it possible to investigate the molecular action of mutagens and carcinogens more closely^{4,5}. For example, there is considerable evidence that some types of lesion in DNA such as UV light-induced pyrimidine dimers and various chemical adducts are blocks to DNA synthesis both *in vivo*^{6–9} and *in vitro*^{10,11}. The available data support the hypothesis that the block occurs at the level of the lesion on the template strand^{10,11}. We have used DNA containing such lesions on a template of known sequence for *in vitro* DNA synthesis by DNA polymerase 1 to investigate the site of the block at the level of the nucleotide sequence. This method allows us to

Fig. 1 Polyacrylamide gel analysis of the product synthesized by *polI* on a DNA template reacted with AAAF. Single-stranded phage Φ X174 DNA ($400 \mu\text{g ml}^{-1}$) was reacted with ^{14}C -AAAF ($50 \mu\text{g ml}^{-1}$) for 4 h at 30°C , extracted 4 times with amyl alcohol, precipitated with ethanol and resuspended in 10 mM Tris-HCl pH 7.5, 0.25 mM EDTA. The extent of reaction, determined from the ratio of ^{14}C c.p.m. to A_{260} was ~ 265 AAAF adducts per Φ X DNA molecule. Double-stranded RF Φ X DNA was digested with *HaeII* endonuclease (BRL) and individual restriction fragments were purified on agarose gels. Restriction fragment 2 (ref. 12) was heated at 100°C for 5 min and annealed to either AAAF-treated or unreacted DNA at 65°C for 90 min (molar ratio 1.2:1). Polymerase reactions were carried out in a volume of $20 \mu\text{l}$ and contained 50 mM Tris-HCl, pH 8.0, 8 mM MgCl_2 , 5 mM dithiothreitol, dATP, dGTP and dCTP, $50 \mu\text{M}$ each, $1\text{--}2 \mu\text{Ci}$ [$\alpha\text{-}^{32}\text{P}$]TTP (about 300 Ci mmol^{-1}), $0.1\text{--}0.2 \mu\text{g}$ DNA and 0.7 units DNA polymerase I (Klenow fragment, Boehringer). Incubation was at room temperature for 15 min and then $2 \mu\text{l}$ 0.5 mM TTP was added, incubation continued for a further 15 min and the reaction was stopped by heating at 65°C for 10 min. One unit of *HaeII* (BRL) was then added and incubated at 37°C for 60 min. For the sequence standards di-deoxyribonucleoside triphosphates were used as described by Sanger *et al.*³. The products were denatured and analysed on a 20% polyacrylamide gel². Lanes Control and AAAF are the products synthesized on untreated and AAAF-reacted templates respectively. Lanes A, C, G and T are the sequence standards produced with the di-deoxy chain terminating nucleotides. Numbering is from the position of the *HaeII* cleavage site.

determine both the site at which lesions capable of blocking synthesis by DNA polymerase occur and exactly where synthesis stops in relation to the lesion.

Φ X174 DNA was used in these experiments as it has already been completely sequenced^{12,13}. The Klenow fragment of *Escherichia coli* *polI* was used as the polymerase for most of our

experiments. The template consisted of single-stranded phage DNA to which individual restriction fragments, obtained by digestion of the double-stranded RF DNA, were annealed. We used fragments produced by the enzyme *HaeII* which cuts Φ X174 RF DNA at eight sites¹². These templates were used for the di-deoxynucleotide chain terminating method of Sanger and Coulson to provide a sequence standard. We found minor discrepancies with the preliminary sequence published by Sanger *et al.*¹²; however, in practically every case these were found to be in complete agreement with the revised sequence¹³. Single-stranded Φ X174 DNA was either UV-irradiated or reacted with *N*-acetoxy-2-acetyl aminofluorene (AAAF) or other carcinogens. The reacted template was then annealed with the priming restriction fragment and the polymerisation reaction carried out as for the sequencing reactions except that the di-deoxynucleotides were omitted.

In the reaction with AAAF-treated DNA a number of bands are seen which do not appear when untreated DNA is used (Fig. 1). These bands in the three cases in which identification is

Fig. 2 Polyacrylamide gel analysis of the products synthesized by *polI* on DNA templates reacted with AAAF or anti-BPDE or irradiated with UV light. For the anti-EPDE template $46 \mu\text{g}$ Φ X DNA was incubated at 37°C with 30 nmol ^{14}C -anti-BPDE in 0.5 ml . At 60-min intervals a further three additions of ^{14}C -anti-BPDE were made and incubation continued for 5 h. The DNA was extracted four times with amyl alcohol and precipitated with ethanol. About 140 anti-BPDE adducts were added per Φ X DNA molecule. The DNA for the UV template was irradiated with 1000 J m^{-2} of UV at a DNA concentration of $100 \mu\text{g ml}^{-1}$. The primer used in this experiment was *HaeII* fragment 5. Reaction conditions were the same as for Fig. 1. Lanes Control, AAAF, BPDE and UV are the products synthesized by *polI* on untreated, AAAF or anti-BPDE-reacted and UV-irradiated DNA templates respectively. Lanes A, C, G and T are the sequence standards.

Fig. 3 The position of chain termination in relation to the sites of lesions in the DNA: diagrammatic representation of data shown in Fig. 2. Potential sites for the formation of *N*-acetyl-*N*-(guan-8-yl)-2-aminofluorene (guanines) and of pyrimidine dimers (adjacent pairs of pyrimidines) are shown along side of the position of bands obtained with synthesis by pol1 on AAAF-reacted or UV-irradiated DNA templates.

possible occur one base before that of a cytosine residue in the sequence standards, that is, synthesis has stopped at the base before a guanine in the DNA template. AAAF has been shown to react predominantly with guanine in DNA to form *N*-acetyl-*N*-(guan-8-yl)-2-aminofluorene^{14,15}. Our results both confirm the known major site of reaction of AAAF in DNA and demonstrate that this lesion is a block to DNA synthesis. Another conclusion that can be drawn from these experiments is that there seems to be no preferential reaction of AAAF with particular guanines in the section of tested DNA, at least in the conditions used here; that is, single-stranded DNA reacted *in vitro*. Bands can be detected corresponding to all the guanines in the region of the template for which the sequence can be resolved, and there is no obvious predominance of any of them. This may simply reflect the very high number of adducts in the DNA (about 1 per 5 guanines) although with a lower number of adducts (about 1 per 30 guanines) no bands at all were detected. There is no indication of lesions blocking synthesis at any position other than guanine. This conclusion was confirmed by an experiment using a different priming fragment (Fig. 2) which included templates either treated with ($\pm$)7,8-dihydroxy-9,10-epoxy-7,8,9,10-tetrahydro benzo(a)pyrene (anti-BPDE) or irradiated with UV light. The pattern of bands obtained in this experiment is shown in Fig. 3. The bands produced with the AAAF-treated template are again consistent with those expected if synthesis terminated one nucleotide before an *N*-acetyl-*N*-(guan-8-yl)-2-aminofluorene residue. A completely different pattern of bands is seen with the UV-irradiated template. Synthesis on such a template terminates one nucleotide before any pair of pyrimidine bases. All three types of pyrimidine dimer, cytosine-cytosine, cytosine-thymine and thymine-thymine, are blocks to DNA synthesis although there is some indication that the bands resulting from thymine-thymine dimers are more prominent, probably due to their faster rate of formation during irradiation¹⁶ and thus more frequent occurrence in the template.

The results with anti-BPDE are more difficult to interpret. Prominent bands occur at the same positions as found with AAAF treatment although many other bands can also be seen. This would suggest that guanine is a major site of reaction for anti-BPDE¹⁷ although reaction also occurs at other bases, notably adenine.

As synthesis stops at the base preceding a guanine with AAAF-treated template DNA and at the base before the first of the two pyrimidine bases with UV-treated template DNA, it is clear that termination occurs without a nucleotide present at the site(s) opposite the lesion. It is possible that DNA polymerase 1 does add nucleotides in this position but that they are rapidly excised by the 3'-5' exonuclease activity of the enzyme due to lack of base pairing¹¹; however, our observation (data not shown) that a DNA polymerase α isolated from human lymphoblastoid cells¹⁸ and having no 3'-5' exonuclease activity gives the same band pattern with UV-irradiated template DNA

as does pol1 suggests that synthesis terminates due to the inability of the enzyme to incorporate nucleotides opposite a non-pairing lesion. We occasionally found additional slightly lighter bands one or even two bases before the main termination bands, for example, in Figs 2 and 3 at positions 15 and 34 with AAAF and at positions 31 and 32 with UV. These may result from degradation by either the 3'-5' exonuclease or residual 5'-3' exonuclease that contaminates some commercial batches of pol1 (Klenow). Degradation by the 5'-3' exonuclease is considered unlikely as treatment at 65 °C before addition of the restriction enzyme completely eliminated spurious bands on the sequence standards caused by this activity but did not affect the extra bands on the AAAF-reacted or UV-irradiated templates.

These experiments are essentially qualitative and do not show that DNA polymerase stops at every lesion; one cannot determine by this method the amount of 'read through'. However, we expect that the method will be useful to distinguish between lesions that are blocks to DNA synthesis and those that are not as well as elucidating the behaviour of different DNA polymerases on encountering a lesion and possible ways in which DNA synthesis may be able to bypass lesions¹⁹.

We thank Dr Geoffrey Grigg for the conversation during which these experiments were devised. The work was supported by an ACS institutional grant (IN-41-R-30) and from NIH (GM 07816-20).

Metastable crystals of β -cyclodextrin complexes and the membrane diffusion model

WE have previously suggested¹ that dimers of β -cyclodextrin (β -CD) may mimic membrane diffusion transport phenomena. This proposal was based on the orientation of guest molecules in the crystalline 3:2 *p*-iodophenol complex with β -CD, with the assumption that complex formation with guest molecules capable of hydrogen bond formation occurs through an initial interaction with one of the hydroxyl groups of β -CD. The 7:14 distribution of hydroxyl groups on the primary and secondary sides of the β -CD torus, respectively, was interpreted as favouring formation of a complex with the hydrogen bonding moiety on the secondary side of the torus. The fact that the guest molecules in the above complex were orientated in the opposite direction was taken as an indication that exchange of guest molecules between a dimeric complex and the solution had occurred. We report here that β -CD inclusion complexes with various guest molecules produce metastable crystals (designated CII) when growth is achieved by slow cooling, and we have determined the crystal structure of an *n*-propanol complex of

this phase. We find that comparison of the structure of this metastable phase and that of the thermodynamically more stable phase¹, CI, provides information relevant to the question of the presence of β -CD dimers in solution; this information is relevant to the suggestion that such dimers mimic bilayer membrane diffusion transport.

CII crystals of the *n*-propanol complex were grown from a 60:40 (v/v) *n*-propanol:water solution of β -CD by slow cooling. Typically, a solution near its boiling point was contained in a beaker sealed with a wax sheet topped with aluminium foil; the beaker was placed in a Dewar flask containing a water bath also near its boiling point. The flask was covered with thermal insulating material and allowed to stand for 1.5–2 d, during which the system cooled to a temperature describable as warm to tepid. Crystals with well formed faces and uniform morphology were routinely obtained in this manner. After several hours at room temperature, these crystals had obviously begun to dissolve and crystals of type CI appeared; their number increased with time as those of type CII decreased until the latter phase had disappeared.

Both crystalline phases were found to display P1 space-group symmetry but to have different unit cell volumes: $V_{CI} = 3,636 \text{ \AA}^3$ and $V_{CII} = 3,346 \text{ \AA}^3$ (both at $\sim 120 \text{ K}$); the lattice parameters for CII are $a = 15.461(2)$, $b = 15.575(3)$, $c = 15.316(3) \text{ \AA}$, $\alpha = 103.98(2)^\circ$, $\beta = 100.92(2)^\circ$ and $\gamma = 104.23(2)^\circ$. The initial crystal structure was solved by the use of

Fig. 1 Stereoscopic projections² of the crystal structure of *n*-propanol complexes of β -CD in thermodynamically stable phase CI and metastable phase CII. To illustrate the packing differences, two β -CD:*n*-propanol dimers have been drawn. The oxygen atoms of their environment (water molecules or adjacent β -CD molecule hydroxyl oxygen atoms) have been drawn. The disorder in the guest molecules is indicated by the size and shape of their thermal parameter representations. Those of phase CI are indicative of anisotropic thermal parameters whereas those of CII correspond to isotropic temperature factors.

Fig. 2 A schematic representation of the principal processes leading to crystals of phases CI (thermodynamically stable) and CII (metastable) as the result of slow cooling of an aqueous solution. The symbols are: β -CD, β -cyclodextrin; G, guest molecules suitable for formation of inclusion complex β -CD·G, which may be of different stoichiometry in the monomeric and dimeric forms; s, solvation molecules (subscripted to indicate possible differences in solvation for the various species indicated). Trends in thermodynamic properties, ΔH , ΔS , and ΔG , are indicated for changes between numbered states.

non-crystallographic symmetry and the known structure of the β -CD dimer from the crystal structure analyses of phase CI, in a manner that will be described in more detail elsewhere. Refinement of the structural model of CII with isotropic temperature factors and a high resolution data set ($2\theta_{\max} = 60^\circ$, MoK $_{\alpha}$ radiation) has converged at $R = 12.0\%$ for 15,000 contributing data. At this stage of the refinement the unit cell composition is $C_{96}H_{172}O_{74} \cdot 18-19H_2O$. Refinement of the structural model for the CI *n*-propanol complex with anisotropic temperature factors is nearing completion. We now believe that the complex contains four disordered *n*-propanol guest molecules, giving a unit cell composition of $C_{96}H_{174}O_{74} \cdot 24H_2O$. The present R value is 8.0% for $\sim 19,300$ contributing reflections ($2\theta_{\max} = 60^\circ$).

Stereoscopic projections² displaying two β -CD dimers and oxygen atoms of their environment are presented for the *n*-propanol- β -CD complexes of phases CI and CII in Fig. 1. It is immediately apparent from the figure that the crystal packing is very different in the two phases. The metastable phase has a channel structure that seems to be similar to the packing reported for other β -CD complexes grown from aqueous solution by slow cooling^{3,4}, whereas phase CI displays a brickwork packing network. Another significant difference between the structures of the two phases is the presence of a water layer between the β -CD dimers in CI and its absence from the metastable phase. We find these structural differences and the metastable property of phase CII intriguing because of the inferences they have for the structure and properties of β -CD complexes in concentrated solutions.

The temperature-solubility gradient displayed by the β -CD:*n*-propanol:water system was used to grow crystals of phase CII. The fact that these crystals are metastable implies that they result from a kinetically rather than thermodynamically controlled process. Figure 2 summarises what we believe to be the principal processes giving rise to phase CII and, subsequently, to phase CI.

Complex formation to give β -CD·G, step 12, is expected⁵ to increase the entropy of the system as the result of release of molecules of solvation from both host and guest and to decrease

the enthalpy by freeing high energy (ref. 5) water molecules from the β -CD torus for subsequent hydrogen bond formation. We suggest that solution molecular dynamics are important in step 23. Water molecules have a considerably higher ($\sim 10\times$) mean velocity than the larger β -CD monomers. At temperatures at which thermal dissociation of hydrogen bonds is prevalent, this velocity difference can be important in determining which molecules form stable interactions. Two properties of β -CD·G monomers favour their association: their similar molecular velocities and the favourable distribution of secondary hydroxyl groups for the formation of multiple interdimer hydrogen bonds; dimerisation is also thermodynamically favourable (see Fig. 2). The inclusion of additional guest molecules in the extended torus of the dimer, step 34, is thermodynamically favourable but not crucial to the remainder of the process. We include it here to account for the four *n*-propanol molecules in these structures. Step 45, crystallisation of phase CII, is the kinetically controlled step in the process and we believe it reflects the solution molecular dynamics described for step 23. This proposal is clearly consistent with the nucleation of phase CII at temperatures well above room temperature.

The metastable character of phase CII crystals thus indicates that another component in the equilibrium becomes important at lower temperature. We suggest that this component is the building in solution of a stable hydration shell over the primary faces of the dimer (a component of step 46). This step may be accompanied by exchange of guest molecules with the solution and may also result in a change in 'stoichiometry' of the dimer. Orientation of hydrophilic substituents of the included molecules towards the primary side of the β -CD torus can be expected to stabilise the hydration layer further by promoting the formation of hydrogen bonds. Crystallisation of the more highly hydrated dimer gives rise to an equilibrium system and the thermodynamically stable phase CI.

We interpret the presence of the β -CD·G dimers in phase CII, and the observation that crystals of this phase dissolve at room temperature to give crystals of a second phase also consisting of β -CD·G dimers, as evidence that the predominant species in concentrated aqueous solutions is the dimer; a recent solution study supports this interpretation⁶.

The orientation of the guest molecules in the two structures also differs but it is inappropriate to take this as evidence for exchange of guest molecules with solution, as the *n*-propanol molecules are sufficiently small to allow their reorientation within the torus. The disorder in the *n*-propanol molecules in phase CI makes it unreliable to assign C and O atoms of the guest molecules in the middle of the dimer. However, it is possible that those in the ends of the dimer are hydrogen bonded to hydrate water molecules. There seems to be a short chain of hydrogen bonds involving the guest molecules and one hydrate molecule in phase CII, but we prefer to wait for the results of further refinement before seeking to analyse it further.

We thank the Deutsche Forschungsgemeinschaft (grant St 230/2) and the Institut für Organische Chemie, Biochemie und Isotopenforschung der Universität Stuttgart for making this research possible.

matters arising

Injection events in ocean history

THE hypothesis that sudden intermittent injections of brackish or hypersaline water from large, temporarily isolated basins into the world ocean may have so altered the existing density stratification that mass extinctions (particularly of the open ocean plankton) resulted^{1,2}, is fraught with possibilities. The mid-Cretaceous anoxic event and the Messinian evaporite event may have workable models, but we are concerned that the models for the Cretaceous-Tertiary boundary and Eocene-Oligocene event have major flaws in that both models require an isolated, fresh to brackish water Arctic Ocean. The best (and perhaps only) available evidence for Maastrichtian time indicates that the open ocean plankton of the Arctic Ocean were neither endemic nor brackish or fresh water. Deep-sea sediment core FL-437 recovered in 1969 from the Alpha Cordillera of the central Arctic Ocean³, contains a rich phytoplankton biota described originally to show specific affinities with late Cretaceous marine silicoflagellates of Russia and California⁴, and subsequently of the south Pacific and Indian Oceans⁵⁻⁷. A study of the abundant diatom flora substantiates these affinities with known normal marine species (J. A. Kitchell and D. L. Clark in preparation). The complex is similar to the middle-late Maastrichtian complexes of California and the Koryak Range of Siberia⁸. Consequently, if a brackish water injection event occurred in the latest Cretaceous, it certainly did not originate from an Arctic basin encompassing the Alpha Cordillera.

The Eocene termination similarly requires an isolated Arctic basin. Unfortunately, neither Eocene nor Oligocene deep-sea sediment has been recovered from the central Arctic, and this model cannot be tested.

However, recent tectonic interpretations suggest that the time of rotation of the Amerasia Basin was pre-late Cretaceous^{9,10}. Detailed tectonic studies in the Bering Strait region support a late Cretaceous compressional event related to opening of the North Atlantic^{11,12}. The post-Miocene benthic foraminifera and ostracode fauna of the Alpha Cordillera

exhibit both endemism and Atlantic affinities¹³. Hence, the palaeontologic data derived from the central Arctic to date, support a transition from Pacific circulation patterns to Atlantic circulation, in conjunction with the time of opening of the North Atlantic. The observed extinctions of plankton species in the North Atlantic during this time interval may consequently represent the results of competitive interactions.

THIERSTEIN REPLIES—There is little doubt that the Arctic Ocean was filled with marine waters at times during the late Cretaceous. In addition to the evidence cited by Clark and Kitchell of reworked late Cretaceous phytoplankton found in Plio-Pleistocene piston-cores^{1,2}, records of Maastrichtian marine microplankton succeeded by dominantly terrestrial palynomorphs are known from several basins in northern Alaska and the Canadian Arctic^{3,4}. The transition from marine to terrestrial deposition in these marginal basins, however, may be time-transgressive and could be due to local tectonic effects^{4,5}. Tectonic activity in conjunction with a worldwide regression would provide the ideal setting for a temporary isolation and subsequent flushing of the Arctic Ocean through, for instance, the McClure graben near the end

of the Mesozoic (refs 6, 7 and H. R. Balkwill, personal communication). Considering the short time estimated necessary for a freshening of the Arctic Ocean⁸ and the comparatively long duration of several million years of phytoplankton zones in the late Cretaceous^{9,10}, the evidence presently available from the Arctic does not preclude a temporary freshening and subsequent flushing of that basin at the very end of the Maastrichtian and Eocene.

Shelf temperatures and reef growth on the south-east Florida coast

LIGHTY *ET AL.* describe a drowned Holocene *Acropora palmata* reef off the south-east Florida coast. In attempting to explain the lack of growth of this structure over the past ~7,000 yr, the authors list papers which they claim support low temperature as the principal limiting factor ("... pronounced temperature fluctuations and unusually cold bottom waters in the shallow waters off south-east Florida are effectively preventing active reef growth north of Miami."). However, none of their references apply to this point. The paper by Taylor and Stewart², for example, deals with upwelling off the north-east and central Florida coast—not

at all in the vicinity of the barrier reef. Similarly, there is no evidence that upwelling significantly alters water temperatures on the south-eastern shelf, although it may do so on the Miami Slope and Terrace³⁻⁵. While Vaughan's data^{6,7} indicate that Fowey Rocks (northern Florida Keys) occasionally becomes cooler than the rest of the Florida Reef Tract, there are indications that this is an atmospheric effect due to an open connection with easily-chilled, shallow bay waters⁸. Vaughan did not measure the temperature north of Fowey Rocks, but assumed the existence of a sharp decrease in winter shelf temperatures north of Miami.

In a more direct investigation of these reefs⁹ 27 species of scleractinians were found and it was noted that "Reduced temperatures ... inhibit coral growth further north, but appear to be insignificant in the area studied." Specifically, this meant that in an 18 month period (1969-70), the minimum bottom temperatures taken *in situ* with minimum-maximum thermometers at depths of up to 44m did not fall below 20°C. Similarly, thermistor arrays with sensors on the reef at Boca Raton and Pompano Beach, Florida, recorded no less than 22.2°C during the winters of 1968, 1969 and 1970^{10,11}. In addition, the unpublished XBT data for February 1973 referred to by Lee and Mooers³ shows the same temperature minimum at reefal depths from Fowey Rocks to Fort Lauderdale (T. Lee, personal communication). [The low datum of 17.04°C at 32 m given in the same paper seems to be a typographical error, judging from the published thermistor temperatures at the same station (T. Lee, personal communication).] These temperatures are not unexpected on such a narrow (3-5 km) continental shelf where tide and wind induced fluctuations are small compared with the influence of the warm Florida Current¹².

While it is clear that some limitation is being placed on coral growth here, there are no data which indicate that temperatures at 15-30 m off south-east Florida are much different from those at the same depth farther south, where it is generally considered that reef growth is appreciable. It would be instructive to determine accretion rates on the deep reefs of the Florida Keys where *Acropora palmata* is as absent as it is on the reefs described by Lighty *et al.*

LIGHTY ET AL. REPLY—In our report¹, we attributed the demise of the shelf-edge *Acropora palmata* (Lamarck) barrier reef off south-east Florida to periods of extensive turbidity and to pronounced decreases in water temperatures during the first flooding of large, relatively flat areas of the shelf by rising seas approximately 7,000 yr ago. We did not suggest, as Goldberg implies, that low shallow-water temperatures were the principal cause of the reef's death. Rather, these cold temperatures were one of at least two unfavourable conditions that apparently existed about 7,000 yr ago, and that today control the distribution of modern *A. palmata* reefs in south Florida².

Goldberg's comments suggest that he has misinterpreted our discussion³ of the role of cold water temperatures in limiting reef growth during modern as well as early Holocene time on the entire south-east Florida shelf north of Miami. Goldberg has directed his attention to present-day temperatures at the shelf edge whereas we were referring to pre-existing temperatures at the shelf edge. The low water temperatures that may have contributed to the death of the shelf-edge reef would have resulted from atmospheric cooling of the large expanses of shallow water that formed when the sea initially flooded the continental shelf. Similar conditions currently exist in large shallow-water areas of south Florida, as shown by minimum water temperatures of 18° or less recorded for 23 winter months between 1954 and 1968 in northern Biscayne Bay near Miami³, and for eight winter months between 1968 and 1971 at more than 40 localities in southern Biscayne Bay⁴.

Furthermore, north of Miami present-day atmospheric cooling of shallow shelf water may be preventing *A. palmata* reef growth on the many submerged ridges in nearshore areas of the south-east Florida shelf^{5,6}. Although water depths are shallow enough for the development of *A. palmata* reefs, none were found during an extensive survey of these inner shelf ridges⁶. Along the shelf edge, however, water temperatures may be more favourable for reef growth, but the present water depths of 15-30 m over the relict barrier reef are well below depths in which an active *A. palmata* reef can exist. The hermatypic coral species found by Goldberg⁷ on the surface of the relict barrier reef were a deep reef fauna which did not

include rapid reef-forming species such as *A. palmata* and *Porites porites* (Pallas). In addition, *Acropora cervicornis* (Lamarck) and *Montastrea annularis* (Ellis and Solander) occurred in very low abundance⁷. Early Holocene radiocarbon dates for samples from close to the surface of the relict barrier reef¹ indicate that the deeper water epifaunal community has contributed no appreciable relief to this shelf-edge structure.

The temperature data to which Goldberg refers are not relevant to our discussion, nor are they as extensive as he suggests. The low values cited for "an 18 month period" do not appear in the report to which he refers. Measurements were made by thermistor probes at only one site, off Boca Raton (ref. 8, p 107), with three probes suspended vertically near the shelf edge at depths of approximately 7.5, 16.5, and 29 m, and not "with sensors on the reef." Temperature profiles along transects of the outer reef were measured only on selected dates by a portable salinometer (ref. 8, p 107, 110).

Therefore, it is evident that only minimal data exist for present-day water temperatures at the shelf edge in this area north of Miami, where depth is the most limiting factor in preventing reef growth. Temperature data are also lacking for the shallow inner shelf areas, where substrates are suitable for reef growth but lack any modern accumulation. Finally, although we cannot determine pre-existing low shallow-water temperatures at the shelf edge, we suggest¹ that they existed and that they were at least partly responsible for the death of the relict barrier reef off south-east Florida.

Bulletin of the Crimean Astrophysical Observatory

(USSR Academy of Sciences)

The Observatory is one of the major centers for
astronomical research in the Soviet Union and
publishes highly detailed reports on research
carried on in its following main departments:

- Stellar Physics
- Physics of Nebulae and Interstellar Space
- Solar Physics
- Radioastronomy and the Ionosphere
- Design of Astronomical Instruments

**"The collection of papers in the BULLETIN
OF THE CRIMEAN ASTROPHYSICAL
OBSERVATORY, providing far more detail than
would be possible in the format of normal
astronomical periodicals, is a most valuable
addition to the astronomical literature."**

Dielectric and Electronic Properties of Biological Materials

by **R. Pethig**, *School of Electronic Engineering Science, University College of North Wales, Bangor.*

Biology at the present time largely concentrates on the molecular and cellular level. One purpose of this book is to give support to the concept that future major advances in the biological and medical sciences may only come about after more attention has been directed towards increasing our knowledge at the submolecular level. This in turn will require increased contributions from other disciplines. At the same time the book provides to those working in the biological and medical sciences an insight into some of the physical and theoretical concepts that will be used by the other disciplines.

Adaptive Environmental Assessment and Management

edited by **C.S. Holling**, *Institute of Animal Resource Ecology, University of British Columbia, Vancouver, Canada.*

This book is on the various methods of environmental impact assessment as a guide to the design of new environmental development and management projects. This approach surveys the features of the environment likely to be affected by the developments under consideration, analyses the information collected, tries to predict the impact of these developments and lays down guidelines or rules for their management.

This book is concerned with practical problems. For example, development in Canada, the management of fisheries, pest control and so on. It is devoted to a general understanding of environmental systems through methods that have worked in the real world with its many uncertainties. It does not reject the concept of environmental impact analysis but rather stresses the need for fundamental understanding of the structure and dynamics of ecosystems. reviews

Survival value of migration

J. R. Krebs

The Evolutionary Ecology of Animal Migration. By R. R. Baker. Pp. 1024. (Hodder and Stoughton: London, 1978.) £35.

MIGRATION is a subject which crops up at every major ethological and ecological conference. Orientation and navigation mechanisms of migratory birds, seasonal migrations of vast herds of African ungulates, and periodic emigrations of microtine rodents are among many migration phenomena which never fail to fascinate zoologists. It is surprising in view of the pervasive interest in migration in one form or another that Baker's book is the only modern attempt to deal with the subject in a comprehensive manner. The book covers a taxonomic range from earthworms to man. It boldly attempts to present a general theory of the survival value of migration, and integrate it with what is known about physiological mechanisms.

It is an awe-inspiring work; impressive in its size (over 1000 pages long, even the figure captions sometimes spread over three pages), the illustrations are excellent, and the detail with which many examples are described is remarkable. At the same time one cannot help feeling that the size and thus inaccessibility of the book will discourage many people from giving it the attention it deserves. Baker could have presented the essence of his argument in a much shorter book and reached a much bigger audience.

Baker starts with a 30 page discussion of the definition of migration. Ornithologists use the term specifically to refer to regular, seasonal, long distance, return movements. These are characteristic, for example, of the many birds breeding in temperate zones and wintering in warmer areas. Insects rather rarely make return journeys (at least within a single individual's lifetime) so that entomologists do not characterise migration by the criterion of return to a starting point. In fact, Baker argues, all the separate features which can be used to characterise migration such as distance, return and periodicity vary along a continuum. The upshot is that migration is defined by Baker in the most general way possible: "the act of moving from one spatial unit to another". This allows Baker to include

both an aphid flitting a few centimetres from one leaf to the next, and an Arctic Tern making a 16,000 km pole to pole trip under the rubric of migration. Although there are obvious disadvantages to such a wide definition (a branch falling off a tree "migrates" in Baker's terms), Baker argues that there may be general rules which apply, as he puts it, "to the black bean aphid, the blue whale and the barnacle".

Baker's general cost-benefit model of migration is developed in the next 50 pages of the book. The essence of the argument is that it is in theory possible to calculate for an individual at any moment in time the expected fitness resulting from staying put, and the expected fitness resulting from a decision to move to a new place. When the expected gain for moving is higher than that for staying, migration will be favoured. Baker derives the basic model of an optimal migration threshold, and then goes on to discuss various ramifications. These include stochastic variation in habitat quality, the effects of competition within a habitat on migration thresholds, and exploratory migration as a method of acquiring information about expected pay-offs. Most of the theoretical arguments are qualitative, and one sometimes feels that a rigorous derivation would make the point more convincing. An example is the statement on p72 that "unpredictable fluctuations in E (the expected fitness consequent upon migration) ... are more likely to lead to a ... distribution of staytimes ... corresponding to the distribution of frequency of different values of E ".

Baker's model of migration is essentially the same as the well known "marginal value theorem" published several years ago by E. L. Charnov, G. A. Parker, and others. Baker's application of the idea to migration in general is perhaps somewhat novel, but to some extent the edge is taken off the theoretical section of the book by the fact that the ideas have already been developed by others.

The remaining 900 pages of the book are entitled "evaluation of the model: examples and analysis". The organisation is mainly taxonomic. As there are virtually no data which can be used to test the model in a rigorous way,

by far and away the bulk of the "evaluation" is in terms of qualitative evidence and *post hoc* interpretation. One quantitative test of the model which Baker describes is the outstanding work of G. A. Parker on dungflies, and this occupies only two or three pages. I feel it could have been given more extensive coverage as it is so central to Baker's theme. Although the literature seems to be well covered, there are some obvious gaps. For example, the section on movement paths in chapter 18 does not refer to J. Paloheimo's theoretical analysis of optimal search paths, or J. N. M. Smith's refined experimental analysis of bird movement tracks. The long section on bird navigation and pigeon-homing makes no reference to the Italian work on scent maps, Keeton's work on release site bias, or Gwinner's re-appraisal of the star map work of Sauer. One general area which did not seem to be covered is the genetics of migration. The theoretical arguments assume that there is genetic variance for migration thresholds, but the work on genetic correlates of emigration in small mammals, for example, is not included.

However, these minor omissions are more than offset by the great diversity of facts and insights in the book. To mention just one example, the discussion of home range and territoriality (pp384-410) places a useful emphasis on the exploratory behaviour of non-territorial individuals. In part, the discussion centres around conditions which will favour a non-territory holder attempting to displace a resident instead of migrating to try and find an empty space elsewhere. Looking at home range defence from the resident's point of view, Baker argues that one of the most general benefits derived from exclusion of others is an increase in the accuracy with which resources in different parts of the home area can be assessed and ranked. If transient individuals are permitted to exploit these resources, then the value of exploration and ranking by the resident is reduced. As with so many of the ideas in the book, there is plenty to stimulate thought and discussion, but no hard evidence.

Baker's discussions of migration in modern industrial human societies is

certain to arouse controversy. He takes the extreme view that our present-day migration patterns are directly determined by natural selection. He also argues that natural selection is still acting in a similar fashion to that experienced by our hunter-gatherer ancestors. The argument is roughly as follows. In ancestral hunter-gatherers, newly formed pairs migrated away from their natal groups to other parts of the home range explored during adolescence. Pairs tended to settle in areas where their expected reproductive success (limited mainly by food supply) was highest. Males tended to explore larger ranges than females, partly because they could increase their reproductive success by incidental copulations on the way. Baker goes on to apply these speculative conclusions to industrial man: "I feel some justification in claiming that the migration pattern shown by modern industrial humans is that evolved during the 10-20 million years of hunting-gathering. All that remains is to consider whether the

selection that is acting at the present time on modern industrial humans is tending to perpetuate or change the pattern." His highly controversial conclusion is that our present-day migration patterns are genetically controlled, hormonally mediated ("part of the physiological syndrome that transforms an individual to physical maturity is a decreasing migration threshold") behaviours. There is likely to be much argument against this conclusion. Even if one accepts in principle that genetic selection can still influence migration behaviour in man (a view for which no evidence is given), it is not at all clear to what extent factors such as extramarital copulation and protein intake alter inclusive fitness.

Although one may not agree with all of Baker's views, the book is thought provoking, and it will be a pity if it is not widely read because of its size and price. □

John R. Krebs is Lecturer in Zoology at the Edward Grey Institute of Field Ornithology, Oxford, UK.

Inherited behaviour and reactions to drugs

Drugs and the Inheritance of Behavior: A Survey of Comparative Psychopharmacogenetics. By P. L. Broadhurst. Pp. 206. (Plenum, New York and London, 1978.) £12.28.

P. L. BROADHURST has written a short but surprisingly complete book in the area of the effects of inherited behaviour on reactions to drugs. The title that he has taken was not his first choice and it is somewhat misleading. As everyone familiar with the field will know, this is a relatively small and new discipline which studies the effect of genotype on an organism's reaction to drugs. Almost all of the work discussed comes from rat and mouse experiments. The title implies that the drugs are altering the inheritance of behaviour, but of course the opposite is the case, it is the influence of inheritance on the response to drugs that is being studied. Dr Broadhurst would have preferred the title *Psychopharmacogenetics* but that title was pre-empted by B. E. Eleftheriou with an edited book (Plenum, New York, 1975). Others, such as McClearn, favour the name "Behavioural Pharmacogenetics" for the area.

Whatever the name, it is a field that has been entered on the one hand by behavioural geneticists often with insufficient knowledge of pharmacology, on the other by pharmacologists with insufficient knowledge of genetics or by psychologists with insufficient knowl-

edge of both of the other two disciplines. Dr Broadhurst's book is replete with examples of the resultant chaos. He is properly critical of the investigators who have perpetrated some of the scientific monstrosities which often seem to have been undertaken with bad design, poor or non-existent controls, poorly analysed and then published repeatedly.

There are, however, numerous examples of well designed and well executed studies. Students and those

Aflatoxins

Aflatoxins: Chemical and Biological Aspects. By J. G. Heathcote and J. R. Hibbert. Pp. 212. (Elsevier, Amsterdam and New York, 1978.) Dfl. 120, \$53.50.

MANY processed food components, and the foods themselves, are potential substrates for moulding by mycotoxin-producing fungi and so it is no small wonder that aflatoxin B, being the most potent hepatocarcinogen in the rat, and related aflatoxins should be a subject of much biological and chemical research.

After opening chapters on the discovery of aflatoxins and their production under natural conditions and in the laboratory the chemistry of these substances is reviewed and their assay by physicochemical techniques and bioassay are described.

Thereafter, sufficient pathology is presented for the non-medical reader to appreciate the general nature of the effects without being blinded by technical jargon. The distinction between acute toxicity and carcinogenicity is made clear.

just entering the field would do well to read this book and take heed of the lessons that it contains. It gives examples of the use of the most popular and powerful genetic techniques including selective breeding, sex differences, strain differences, diallel crosses and recombinant inbreeding.

For the novice to the field the precautions and controls that are outlined seem excessive and unnecessary, however, the experiments usually require months if not years of study and are often exceedingly expensive. The techniques are extremely powerful but much time and money can be wasted unless careful planning is done before rather than during or after the experiment.

The book has the decided advantage of being written by one individual with a consistent style and approach. It also has the advantage over edited books of being less self-serving and providing a broad overview rather than a series of narrow reports. In his desire to be complete, Dr Broadhurst has done a remarkable job, but therein also lies one of the criticisms of the book. In his zeal he has often used information contained in abstracts. Generally this is done because the data has not appeared in an edited journal. Thus, some of the conclusions reached by Dr Broadhurst rest on some rather thin ice.

Richard A. Deltich

Richard A. Deltich is Professor and Vice-Chairman of Pharmacology at the University of Colorado School of Medicine, and Research Associate of the Institute for Behavioral Genetics, Denver, Colorado.

The chapters on biochemistry and metabolism perhaps constitute the most intellectually stimulating feature of this book and the authors, who have worked in the field, have not hesitated to make certain value judgements. They are cautious concerning the significance of the elusive derivative aflatoxin B₁-2-3 epoxide in acute toxicity and offer hemiacetal derivatives of aflatoxin as candidates for the role of carcinogen.

The book concludes with a well illustrated review of the biosynthesis of the aflatoxins and their interrelationships, followed by a chapter on control of aflatoxin contamination and current attempts at detoxification of foods.

The style of the text is clear and readable and typographical errors are rare. Those concerned with food science should read this book. I also suspect that the general reader could catch from it the fascination of aflatoxins and their mode of action.

P. G. Mantle

P. G. Mantle is Senior Tutor in Biochemistry at Imperial College, University of London, UK.

Oxford Books for Students

Physical Chemistry

P. W. Atkins

'It is a book of its time not only in content and outlook but in format and style too . . . could well become a milestone in the development of text books of physical chemistry.' *Chemistry in Britain*. 'An important and original work.' *Education in Chemistry*. 'The author is to be congratulated on the production of such a good text and the publishers for its presentation at a price within the reach of students' *British Book News*. £17.50 paper covers £7.95

Solutions Manual for Physical Chemistry

P. W. Atkins

This manual contains the author's detailed solutions of almost every one of the 1,060 problems contained in his textbook *Physical Chemistry*. It will be invaluable both to the instructors and lecturers who have adopted the parent text and to the students who use it themselves. Illustrated paper covers £4.50

Primary Metabolism

A Mechanistic Approach
J. Staunton

The traditional line of demarcation between biochemistry and chemistry has dissolved in recent years as chemists and biochemists have joined forces in investigating the mechanisms of reactions which take place in living systems. This book introduces this area of common interest to students of both chemistry and biochemistry. The later chapters take account of the biological dimension by tracing representative metabolic pathways step by step to show how the constituent reactions mesh together to form a coherent metabolic machine. £6.50 *Oxford Chemistry Series*

Secondary Metabolism

J. Mann

'It is encouraging to see published a book such as Dr Mann's, which is designed for the undergraduate and beginning researcher. His book is very well put together and should facilitate and encourage the preparation of undergraduate courses on modern natural products chemistry' *Chemistry in Britain*. £9.75 *Oxford Chemistry Series*

Thermodynamics and Statistical Mechanics

P. T. Landsberg

The basic ideas and mathematical formulations of thermodynamics are presented here in a concise and modern way. Topics covered include: negative temperatures; negative heat capacities; special and general relativistic effects; black hole thermodynamics; gravitational collapse; energy conversion problems; and efficiencies including simple heat pump theory. £8.50

The Solid State

An Introduction to the Physics of Crystals for Students of Physics, Materials Science, and Engineering

H. M. Rosenberg

The topics covered include basic crystal structure, diffraction of waves, dislocations, specific heat, phonons, thermal and electrical conductivity, the physics of p-n semiconductor junctions, and magnetic and dielectric properties. For the second edition a chapter on superconductivity has been added. £5.50 paper covers £2.55 *Oxford Physics Series*

Physical and Engineering Science for Technicians, Level I

R. J. Besanko and T. H. Jenkins

This new version of *General Engineering Science* is designed to cover the units in physical science and engineering science at Level 1 for students taking TEC Certificate and Diploma Programmes. Some additional material is included to satisfy college-devised units, and the book is also suitable for other courses at this level. Paper covers £2.95

Scientific Models and Man

The Herbert Spencer Lectures, 1976
Edited by Henry Harris

In these lectures a group of distinguished men from different disciplines describe how current work in their own subject is changing their view of the world. Scientific models have been enormously influential in transforming the way in which we look at ourselves and at the universe: this book gives some indication of the way the world is going to look tomorrow. £3.25

THESE AND MORE WILL BE APPEARING SHORTLY IN THE INAUGURAL ISSUE OF

Trends in Pharmacological Sciences

**Inaugural issue
now available!**

Published by Elsevier in association with the International Union of Pharmacologists

a new and completely different publication for pharmacologists

Conceived as a result of the explosive increase in pharmacological activity, 'TIPS' aims to illuminate the many common underlying themes of pharmacology - in an attempt to break down the communication barriers that have developed as a consequence of specialisation, geographical dispersion, and environmental diversification. Embracing every major aspect of the field from basic pharmacology, molecular pharmacology, drug monitoring and therapeutics to toxicology, TIPS will keep the pharmacologist informed and entertained with reviews, news articles, features and book reviews. A unique combination of scholarly innovation and imaginative enter-

prise, supported by a skilled and decisive editorial team, 'TIPS' promises to become the pivot of the pharmacology world, and as such essential reading for anyone wishing to keep abreast of developments in the area

Chemisorption of gases on metals

Chemisorption of Gases on Metals. By F. C. Tompkins. Pp. 370. (Academic: London, New York and San Francisco, 1978) £16.80.

MAJOR advances in our knowledge and understanding of the chemisorption of gases on metals have occurred during the past decade. The elemental composition, crystallography, and the electronic and vibrational properties of surface layers on defined single crystal faces are now measurable, and a wealth of detailed information is available in the research literature. But for the advanced undergraduate or beginning postgraduate student there has been a serious lack of comprehensive introductory texts in which the theoretical bases and experimental methods of the newer physical techniques are clearly explained and in which the contributions of these techniques are placed in perspective with the traditional methods of surface study.

Professor Tompkins' book is intended to fill this gap. Its plan is excellent. The early chapters deal with the terminology of adsorption, methods of preparing clean surfaces, the kinetics of adsorption and desorption, isotherms and heats of adsorption, and the thermodynamics and statistical thermodynamics of adsorption. These chapters provide a natural link with earlier texts. They are followed by outlines of the electronic theory of metals and metal surfaces. The remaining half of the book is composed of short chapters dealing with work functions, magnetic susceptibility, electrical conductivity, low energy electron diffraction, infrared spectroscopy, field emission and field ion microscopy, Auger electron spectroscopy, photoelectron spectroscopy, ion neutralisation spectroscopy, electron energy loss and appearance potential spectroscopies, and a short review of some experimental results for adsorbates on tungsten.

The book conveys quite well the interplay of theory and experiment in modern surface science, and gives due emphasis to the methods which have proven most fruitful. However, it is neither as comprehensive nor as up to date as one might have expected. Ion-scattering and secondary ion mass spectrometry are completely omitted, as is cathodoluminescence, and the only reference to high resolution electron energy loss spectroscopy is the early paper of Propst and Piper (1967). Although published towards the end of 1978, the book contains very few ref-

erences dated after 1975. Except for the treatment of ultraviolet photoelectron spectroscopy, it is not appreciably more up to date than Wedler's *Chemisorption: An Experimental Approach* (Butterworths, 1976) and it is less comprehensive in its coverage of experimental methods. More emphasis is placed by Tompkins on the theoretical background, particularly the electronic properties of metals and surfaces. However, the level of the theory is sometimes too ambitious for its proper development in an intro-

ductory book of this scope and the student will often be baffled unless he pursues the references.

Despite these shortcomings the book is a welcome addition to the literature on chemisorption. The student will find it a useful guide to an increasingly interdisciplinary field of physics and chemistry.

J. Pritchard

J. Pritchard is Professor of Physical Chemistry at Queen Mary College, University of London, UK.

Account of the bumblebee

The Life of the Bumblebee. By D. V. Alford. Pp. 80. (Davis-Poynter: London, 1978) £3.95.

THIS is a popularised and much abbreviated version of D. V. Alford's *Bumblebees* which was published by Davis-Poynter in 1975. To help the general reader Alford begins by reviewing the features of insects in general, and bumblebees in particular. He then follows the usual and successful formula of tracing the biology of the colony from its initiation in spring, its growth to maturity, and the production of males and queens. He goes on to discuss further topics (including temperature regulation, foraging, orientation, mating and hibernation) and refers to most of the more important recent findings as well as the better

known and established aspects of bumblebee biology.

The final chapter entitled "Bumblebees and Man" is most valuable in drawing the reader's attention to the importance of bumblebees as pollinators of our crops, and the need whenever possible to protect them from the hazards of insecticides, to replace sources of forage destroyed by herbicides and intensive cultivation, and to provide sites suitable for nesting and hibernation. Appendices describe the 25 British species of bumblebees. There are eight pages of good black and white photographs.

In general Alford is to be congratulated in avoiding placing undue emphasis on his own particular interests and in presenting a well balanced accurate and readable account of the bumblebee.

John B. Free is at Rothamsted Experimental Station, Harpenden, UK.

Biological identification methods

Biological Identification: The Principles and Practice of Identification Methods in Biology. By R. J. Pankhurst. Pp. 104. (Edward Arnold: London, 1978.) Paperback £3.20.

SYSTEMATICS as an approach to the teaching of the biologicals was becoming unpopular in the 1960s. Memory-taxing, as then taught, it carried a flavour of the elite natural history museums and culture collections: the spirit of Robbins was moving university teachers towards molecular biology and genetics which could, in some fashion, be assimilated by the many.

Meanwhile, computers were making possible numerical, multivariate and probabilistic treatments of biological classification and identification. It has taken over a decade for this to penetrate university teaching and by now there is a shortage of young systematists with an interest in the identification craft.

R. J. Pankhurst's compact book on biological identification methods begins with a splendidly lucid section on the use and construction of keys, taking British species of the genus *Epilobium* as a running example. If the rest were as easy to understand, one could begin to see a very satisfying second-year biology degree module in general systematics drawing on the second edition of C. Jeffrey's *Ecological Nomenclature* (Edward Arnold: London, 1977) for nomenclature, P. H. A. Sneath and R. R. Sokal's *Numerical Taxonomy* (Freeman: Reading, 1973) for classification, and Pankhurst for identification. Lecturers should buy their copy well ahead of the students and settle down to some supplementary reading (the short bibliography is well chosen): the section on probabilistic methods drawing on Bayes' theorem, for a start, will need cracking by a worked-out example, that given (Fig. 16) being just a section of a computer print-out, understandable only by the initiated.

Monothetic and polythetic methods, explained on page 3, would have been an academically sound way of arranging the core of the work. Instead, the

central chapters focus respectively on "conventional" and "automatic" methods: the latter "may or must involve calculations . . . so that the use of a computer is usual". Though it perhaps looks sensibly down-to-earth, this is a comparison not of identification methods but of the ways in which we find it convenient to go about them, and it leads to some confusion. Diagnostic keys are "conventional", are they not? But, wait, we can programme computers to construct keys, so that must be "automatic". Matching methods, now these are certainly "automatic": botheration, they have to go in the "conventional" section as well because we can identify by comparison without calculation. And so on, until it must

dawn on the undergraduate or advanced school student that it is identification logic to which he should address himself, not the fuss about computing and programming language (leading, incidentally, to a strange Fig 18 which actually suggests that "on-line" is a method of biological identification).

It will be observed that the reviewer has been stimulated. So will be the many others who buy this interesting, thought-provoking volume, they, too, will have to work hard.

J. E. Smith

J. E. Smith is Professor of Microbiology at the University of Surrey, Guildford, UK.

Ecological methods

Ecological Methods, with Particular Reference to the Study of Insect Populations. Second edition. By T. R. E. Southwood. Pp. 524. (Chapman and Hall: London, 1978) £10.

It is a mark of the uniqueness of this book that in the 12 years since the first edition no competitor volume has emerged that covers such a wide field. Professor Southwood is just as much at home discussing the idiosyncracies of insect trap construction as he is comparing indices of diversity.

The book is well described by its title, and like many compendia will be most useful to the expert or semi-expert. The sort of methods we choose are influenced by our current understanding of the ecological world around us. Nevertheless, in many asides the author does try to redress the balance, pointing out the relative merits of the different techniques, what they can and cannot do. It is here that the book will also be useful to the beginner.

In the past 12 years there has been a dramatic but allometric growth of ecology in two quite different areas. On the one hand the subject has im-

pinged more on public consciousness; on the other, the rapid development of computers and electronic calculators has stimulated much mathematical modelling and analysis. The result is that the scope of ecology and of this second edition is much wider than ever before.

Every chapter has been updated and new sections added, especially on dispersion, capture-recapture methods, components of predator-prey interaction, and dispersal. In particular, recent growth in the methods of construction of life-budgets, systems analysis, descriptions of diversity and species-packing models now allow Professor Southwood to crystallise out a conceptual framework for discussion which was not possible before.

Theoretical astrophysics

Theoretical Principles in Astrophysics and Relativity. Edited by N. R. Lebovitz, W. H. Reid and P. O. Vandervoort. Pp. 257. (University of Chicago Press: Chicago and London, 1978) £16.10; \$23.

Theoretical Principles in Astrophysics and Relativity offers yet another collection of papers from a conference, this one held in honour of Professor S. Chandrasekhar's 65th birthday in 1975. I found it a distinct improvement on the usual hotch-potch of disparate lectures re-hashed for the wider public with a minimum of editorial tinkering. Firstly, the book is better produced than most conference reports (which usually resemble a wedge of preprints glued together)—which probably accounts for the immense delay in publication. More importantly, however, the articles are mainly of a review rather than research variety; this is fortunate as nearly four years have

A reviewer must also criticise. The greatly expanded field of the subject (1,000 new references, with few deletions from the first edition) is covered in the space of 130 extra pages. The pace of the discussion is therefore fast and, occasionally, confusing. There are omissions (for example, the log normal distribution is mentioned twice, on pp33 and 424, without its basic model) and repetitions (for example, equations 2.26, 2.27, 2.29 and 2.30 re-appear as equations 2.37, 2.38, 2.41 and 2.42); and occasionally parameters are ill-defined (for example, I_m of equation 9.28 and S_T of 13.1) or, together with variables, given different symbols in the text and figures (for example, q and Q in Table 9.1 and equation 9.6; N_F , N_R and P_L , P_R on p382 and Fig. 10.8). Generations of students will now continue to write, incorrectly, of density dependence (Fig. 10.7, in contrast to Fig. 89 of the first edition) and of the Shannon-Weaver rather than Shannon-Wiener function (p426). There are also several small, typographical errors.

None of this, however, detracts from the significant contribution of this volume. The author and publishers are to be congratulated on producing an expanded second edition at less than the price of the final printing of the first. By far the best value on any ecologist's bookshelf.

D. J. Rogers

D. J. Rogers is Lecturer in Entomology at the University of Oxford, UK.

elapsed since the lectures were prepared.

I found the paper on stellar dynamics by Contopoulos especially lucid, and was surprised to see a very formal mathematical paper by Mullikin on the very physical subject of radiative transfer. There is a nice review by Thorne on various phenomena in astrophysics in which general relativity plays a central role, looking all the more relevant with the recent probable discovery of gravitational radiation. The article on singularities in spacetime by Penrose is masterly and thought provoking.

The range of topics covered in the conference was fairly wide, and the articles necessarily somewhat superficial. The book does have, however, a rather more permanent quality about it than comparable proceedings, and is certainly good introductory reading for a host of topics in astrophysics and cosmology. At £16.10, it is not overpriced for such a well-produced format.

P. C. W. Davies

P. C. W. Davies is Lecturer in the Department of Mathematics at King's College, University of London, UK.

● The US edition of *The Climatic Threat* by John Gribbin (for review, see *Nature*, 272, 788; 1978) has been published as *What's Wrong with Our Weather?* by Scribners: New York (\$9.95).

○ The price of *Principles of Chemical Kinetics* (for review, see *Nature*, 278, 194, 1979) was incorrectly quoted. This should be £12.65.

● The US edition of *The Visible College* by Gary Werskey (for review, see *Nature*, 276, 136; 1978) will be published in May by Holt, Rinehart and Winston.

QUEENSLAND INSTITUTE OF MEDICAL RESEARCH PRINCIPAL MEDICAL RESEARCH FELLOW (2 Positions)

Applications are invited for two senior positions from medically qualified investigators registrable in Queensland, Australia. Applicants should have extensive research experience in appropriate fields of medical science and will be expected to establish their own units within the Institute. Clinical association with a major teaching hospital is negotiable.

The Institute currently has commitments in infectious disease, oncology, molecular biology and genetics, with a deep interest in the application of medical science in the context of epidemiology of disease, both in Australia and in the Asian-Pacific region.

Appointment is initially for 5 years, renewable, with a salary of \$33,063 p.a.

Applicants should forward copies of their curriculum vitae, together with the names and addresses of at least 3 professional referees to Dr C. Kidson, Director, Queensland Institute of Medical Research, Brisbane, 4006, Australia, by May 30, 1979. 414(A)

BRUNEL UNIVERSITY LECTURESHIPS IN THE SCHOOL OF BIOLOGICAL SCIENCES

(1) Applications are invited for a lectureship in the Department of Applied Biology. An interest in teaching and research in the general field of Eukaryote Genetics will be a decided advantage.

(2) Applications are invited for a lectureship in the Department of Biochemistry.

The salary for both posts will be on the Lecturer scale £3,883 to £7,754 per annum plus £502 London Allowance.

Write for application form and further details for both posts to the Assistant Secretary (Establishment), Brunel University, Uxbridge, Middlesex UB8 3PH or telephone Uxbridge 37188, extension 49. Closing date May 18, 1979. 372(A)

WESTMINSTER MEDICAL SCHOOL RESEARCH ASSISTANT

Organic Chemist or Biochemist (would be suitable for recent graduate or for a person graduating this Summer).

Required to join a small team working on pigment changes in disease. Work will include the isolation and assay of pigment intermediates from the body fluids of patients undergoing treatment. Post available for one year, initially.

Salary on Whitley Council Scale for Hospital Biochemists.

Applications with curriculum vitae and the names of two referees, to Professor J. R. Hobbs, Department of Chemical Pathology, Westminster Medical School, 17 Page Street, London SW1P 2AR, by April 30, 1979. 425(A)

MEDICAL RESEARCH COUNCIL RADIOBIOLOGY UNIT, HARWELL MAMMALIAN GENETICIST OR CYTOGENETICIST

A scientist is needed to join a group studying the genetic effects of radiation and other mutagenic agents in mammals. The emphasis is on methods of exploring the sensitivity to mutagenesis of germ cells of different sexes, developmental stages and species in the intact animal. Formal genetics and cytogenetics relevant to the mutagenesis work are also included. Candidates with experience of genetics of higher organisms, or of handling rodent chromosomes, at either meiotic or mitotic stages, would be at an advantage.

Possible subjects of research include:

(1) Comparison of the sensitivity to mutagens of various mammalian species, with particular emphasis on methods of studying chromosome changes in oocytes and early embryos;

(2) Studies of the causes of chromosomal non-disjunction in mammals;

(3) Factors affecting the sensitivity of oocytes to mutagenesis.

There are excellent research facilities. The Unit also includes groups studying cell mutation, cytogenetics, pathology, and effects of radionuclides.

Applicants should hold a relevant good honours degree, with three years' research experience, and preferably a Ph.D. Salary and conditions of service according to M.R.C. non-clinical scientific scales. Hostel accommodation for single, or housing for married people, may be available.

Applications, with curriculum vitae and names of two referees, should be sent to Administrator, M.R.C. Radiobiology Unit, Harwell, Didcot, Oxon OX11 0RD, from whom further particulars may be obtained. 429(A)

MEDICAL RESEARCH COUNCIL LABORATORY ANIMALS CENTRE TECHNICIAN

There is a vacancy in the Genetics Department for a technician to assist in the institution of systems of genetic monitoring of small laboratory animals. Experience in immunological and electrophoretic techniques would be an advantage. An HNC or equivalent qualification is essential.

Incremental salary in the range £3,261 to £4,680 plus £354 London Weighting. Contributory superannuation scheme.

Applications to The Chief Technician's Office, Laboratory Animals Centre, Woodmansterne Road, Carshalton, Surrey SM3 4EF

APPOINTMENTS VACANT

UNIVERSITY OF NOTTINGHAM School of Agriculture DEPARTMENT OF PHYSIOLOGY AND ENVIRONMENTAL STUDIES DEMONSTRATORS IN ANIMAL PHYSIOLOGY

2 Demonstrator posts
are available

1: Demonstrator—Available immediately to assist in lectures, tutorials and demonstrations in animal physiology. Applicants should be trained in human or animal physiology or veterinary science and should preferably have gained a Ph.D. research facilities in animal physiology are available. The post is for two years. Salary scale £3,384 to £3,883 per annum.

2: Junior Demonstrator—To assist in tutorials, demonstrations and laboratory work. Post available from August, for up to three years. Facilities available for post-graduate research. Honours candidates graduating this year are encouraged to apply. Salary scale £3,085.

Further particulars and forms of application from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD. Not to be returned later than May 7, 1979. Ref No' 681.

420(A)

UNIVERSITY OF CAMBRIDGE DEPARTMENT OF PHYSIOLOGY Applications are invited for the office of

UNIVERSITY DEMONSTRATOR IN THE DEPARTMENT OF PHYSIOLOGY

Candidates should hold a Ph.D. degree, or a Medical or Veterinary qualification, or be on the point of obtaining one. The person appointed will be expected to assist with the teaching of neurophysiology and the functioning of the nervous system, and should have research interests in this general field.

The initial appointment will be for three years from October 1, 1979. The pensionable stipend for a University Demonstrator will be on a scale of £4,133 rising by four annual increments to £5,129 (under review), with initial placing above the minimum where appropriate. The maximum tenure of a University Demonstratorship is five years. A grant is made towards removal expenses.

Candidates should send 12 copies of their application together with the names of not more than three referees to Mr G. R. Anderson, General Board Office, The Old Schools, Cambridge CB2 1TT, from whom further information can be obtained to arrive not later than May 25, 1979. 413(A)

oxford polytechnic

Faculty of Technology

Head of Department of Geology and Physical Sciences (Grade VI)

A new department is being established from September 1, 1979. The person appointed to this post, while being the administrative Head of the Department, will also be expected to offer academic leadership in at least one major area of the department's work. Applicants should have strong academic and research interests.

Salary: Head of Department (Grade VI) £9,345 to £10,305 (under review from April 1, 1979).

Applications, including a curriculum vitae and the names of three referees, should be sent by May 15, 1979, to the

Dean of Faculty of Technology,
Oxford Polytechnic,
Oxford OX3 0PB,

from whom further particulars and application forms may be obtained.

417(A)

Universiteit van Amsterdam

On the staff of the Research Group of Special Botany (vakgroep Bijzondere Plantkunde) there is a vacancy to be filled of

senior lecturer/reader (m/f) in special botany

The candidate would preferably have to be a

plant ecologist or
vegetation ecologist

(with qualifications on DSc level) who is capable of and will agree to

- taking charge of the section Botanical Ecology of the above-mentioned study group
- doing research on structure and dynamics of vegetation in mire and bog ecosystems
- taking care of the teaching plant and vegetation ecology.

Candidates for this function and those who may recommend suitable candidates are requested to apply (or to advise) within four weeks to the Nomination Committee, attention Prof. Dr. T. van der Hammen, Hugo de Vries-Laboratorium, Sarphatistraat 221, 1018 BX Amsterdam, The Netherlands.

W44(A)

ARC, COMPTON

A CELL BIOLOGIST

is required in the Department of Microbiology. The appointee will be a member of the Scrapie Project Group and required to collaborate in studies of the pathogenesis of scrapie, particularly as it may involve the lymphoreticular system. Duties will also include assistance in the development of improved cell culture systems for the scrapie agent.

Candidates should have a first or upper second class degree in an appropriate biological subject preferably including cellular immunology. At least 2 years relevant postgraduate research or other approved experience is required for appointment as H.S.O., with 4 years for S.S.O.

The successful applicant will be appointed either as a Higher Scientific Officer (Salary scale £4,101 to £5,448 p.a.) or as a Senior Scientific Officer (Salary scale £5,154 to £6,898 p.a.), depending on experience. Non-contributory pension scheme.

Application forms from the Secretary, Institute for Research on Animal Diseases, Compton, Nr Newbury, Berkshire, quoting reference 279.

397(A)

M.R.C. CLINICAL RESEARCH CENTRE (Northwick Park Hospital) Watford Road, Harrow, Middx. HA1 3UJ KERATIN PROTEIN CHEMIST

required to join Dermatological Group with special interest in Collagen Chemistry and related diseases. The appointee should develop methods of Keratin Protein separation which would allow examination of certain inherited and acquired epidermal diseases at a molecular level. This is a limited term appointment for four to five years, depending on age and experience. Salary within the range £5,367 to £7,754 plus £450 L.A. Application form and further details obtainable from Mrs J. Tucker-Bull. Please quote Ref. 110/1/4178. Closing date April 23, 1979. 376(A)

POSTDOCTORAL POSITIONS AT PENNSYLVANIA STATE

Theoretical studies of scattering of high energy ions (500-5,000 eV) from solid surfaces with the objective of understanding surface structure and bonding. A background in scattering theory, electronic processes and/or electronic structure would be desirable. The starting salary is \$11,000 per annum.

Please send a curriculum vitae and two letters of reference to Professor Barbara J. Garrison, Department of Chemistry, 152 Davey Laboratory, University Park, Pa. 16802.

Applications and nominations should be received by May 15. The Chemistry Department reserves the right to continue to process applications and nominations until the position is filled.

The Pennsylvania State University is an affirmative-action, equal-opportunity employer. W61(A)

UNIVERSITY COLLEGE CARDIFF

Applications are invited from graduates or prospective graduates for the post of

TUTORIAL FELLOW in the

DEPARTMENT OF BIOCHEMISTRY.

The appointee will have a First or Upper 2nd Class Honours Degree and will be permitted to register for a Ph.D. There will be some limited teaching duties and the appointee will join Prof. K. S. Dodgson's research group in studies on enzymes involved in the biodegradation of detergents.

The appointment will be for a period of three years. Salary range £3,384 to £3,883 per annum (under review). Duties to commence October 1, 1979.

Applications (two copies), together with the names and addresses of two referees, should be forwarded to the Vice-Principal (Administration) and Registrar, University College, P.O. Box 78, Cardiff CF1 1XL, from whom further particulars may be obtained. Closing date, May 18, 1979. Reference 1761. 418(A)

TECHNICIAN Grade 4 required in Department of Pharmacology to run teaching laboratories for Science and Pre-clinical Medical Students. Previous experience in Pharmacological/Physiological techniques essential. Five weeks annual paid holiday plus statutory and customary days providing a week at Christmas and Easter. Salary in range £3,746 to £4,232 inclusive of London Weighting. Application forms from Personnel Officer (Technical Staff FE7), University College London, Gower Street, WC1E 6BT. 416(A)

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL (University of London) LONDON W1N 8AA SUB-DEPARTMENT OF MOLECULAR BIOPHYSICS

Applications are invited from graduate bio-scientists, preferably with research experience, for a post of

RESEARCH ASSISTANT

within the sub-department of Molecular Biophysics. The appointment, for two years, will be directed initially towards the application of modelling and optimisation techniques to radio-isotopic analytical methods, and ultimately to studies into the modelling of endocrinological control systems. Competence in FORTRAN programming, handling of differential equations, numerical methods, and particularly statistical techniques, will be advantageous. The work, which is supported by the D.H.S.S., will appeal to biological scientists with some mathematical ability. Salary, according to age and experience, but within the range £3,858 to £5,340 (including London Allowance).

Applications, including a curriculum vitae and the names and addresses of two referees, to Professor R. P. Ekins, at the above address by April 20, 1979. 394(A)

UNIVERSITY OF DURHAM DEPARTMENT OF EXTRA-MURAL STUDIES

Applications are invited for the post of
STAFF TUTOR

in Biological Sciences (Zoology) to develop further a wide range of courses for both the general public and specialist groups. Experience in teaching adults is desirable but not essential.

Salary on the scale £3,883 to £7,754 per annum (under review) plus superannuation.

Applications (three copies) naming three referees should be sent by April 21, 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. 281(A)

UNIVERSITY OF LEICESTER

DEPARTMENT OF GENETICS

Applications are invited for a

POSTDOCTORAL RESEARCH ASSOCIATE

to work on an M.R.C.-supported project on the mechanism of action of penicillin and the use of this antibiotic to the processes of cell division and shape determination in *Escherichia coli*.

The position is tenable until October 1981 on the range for Research Associates, £3,883 to £6,555. Applications, including the names of two referees, should be sent to Dr Brian G. Spratt at the Department of Genetics, University of Leicester, Leicester LE1 7RH. 296(A)

BLOOD GROUP REFERENCE LABORATORY

SCIENTIFIC OFFICER

A graduate is required for research and development related to the production of anti-globulin reagents for use in blood transfusion laboratories. Some experience in immunochemistry, protein purification or radioimmunoassay desirable, but not essential.

Applications in writing with details of experience and the names of two referees to Miss K. Lomas, Blood Group Reference Laboratory, Catliff Road, off Ebury Bridge Road, London SW1W 8QJ. 354(A)

The Research Organisation of an internationally recognised European
Pharmaceutical Group located in

PARIS

requires a

**SENIOR
CARDIOVASCULAR
PHARMACOLOGIST**

to join its Department of Biology

The high success rate and rapid growth of this pharmaceutical group is related to the quality of people they employ and their continued commitment to research and development.

For this key position in the Cardiovascular Group we require a professional and highly motivated scientist who will be responsible for various projects within the group and should also be able to conduct independent research programmes. Applicants can be either male or female and should have relevant postdoctoral experience (a maximum of five years). It is essential that the candidate should have experience of the pharmaceutical industry.

A realistic salary can be expected and relocation assistance will be available with other financial benefits.

All applications will be treated in the strictest confidence and should be sent directly to:

"NATURE"
c/o Box No. W59(A)
3 DYERS BUILDINGS
HOLBORN, LONDON
EC1N 2NR

The Polytechnic of North London

Department of Chemistry

Technical staff are required for interesting and varied work in modern and well-equipped laboratories.

LABORATORY TECHNICIAN GRADE 5:

To be responsible for the organisation and daily running of undergraduate and research laboratories; and to participate in advanced work and research projects which may involve preparative chemistry and the operation of complex research equipment.

The technician should preferably hold HNC in Chemistry (or C & G Pt. II or a recognised equivalent) and have 8 years' laboratory experience. (Ref 2/79)

LABORATORY TECHNICIAN GRADE 4:

To be responsible for the organisation and daily running of an undergraduate laboratory, with duties in research laboratories involving preparative chemistry and the operation of scientific instruments.

The technician should have passed at least: GCE with two "A" levels, ONC/OND, C & G Pt. I or a recognised equivalent, and have 7 years' laboratory experience. (Ref 3/79)

LABORATORY TECHNICIAN GRADE 3:

To work in the undergraduate and research laboratories, providing technical service and assistance in operating and maintaining complex equipment.

The technician should have passed at least: GCE with two "A" levels, ONC/OND, C & G Pt. I or a recognised equivalent and have 3-5 years' relevant experience. (Ref 4/79)

Further specialised training will be given where appropriate.

Salaries Scales (including London weighting).

Grade 5 £3,675—£4,212

Grade 4 £3,441—£3,891

Grade 3 £3,162—£3,549

Further details and application forms may be obtained from:

Head of Department of Chemistry
The Polytechnic of North London
Holloway Road, London N7 8DB.

378(A)

THE WORLD HEALTH ORGANIZATION

Requires an EDITOR for its Office of Publications at Headquarters, Geneva. The incumbent will have editorial responsibility for the content, style and presentation of WHO publications, and will follow publications through all stages of preparation; on the basis of background texts or interviews; will write articles, reviews, publicity material, etc., for publication; may be required to serve as a precis, minute or report writer at meetings. Applicants should have a university degree or equivalent, and experience in the editing of publications of a technical nature, in writing articles and/or preparing of records of international conferences. Excellent knowledge of English essential and good knowledge of French.

Applications, quoting reference VNP79/10, should be addressed to:

The World Health Organization, Personnel
CH-1211 Genève 27

Not later than 30 April 1979.

Only candidates under serious consideration will be contacted.

W51(A)

UNIVERSITY OF EDINBURGH

Re-advertisement

LECTURER

IN SEED TECHNOLOGY

This post is being re-advertised as it is now possible to offer normal tenure and, therefore, the date for applications is being extended to May 9.

The Edinburgh School of Agriculture invites applications for a University Lectureship with responsibility for the M.Sc./Diploma Course in Seed Technology. This 12-month postgraduate course, which is supported by O.D.M., has emphasis on technical management for seed production, particularly overseas. Applicants should be University graduates with experience of seed production overseas.

This appointment will commence at the latest from October 1979 and will be on the Lecturer scale £3,883 to £7,754.

Further particulars can be obtained from the Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh. Please state Ref. No. 1013 with application. 428(A)

WELSH NATIONAL SCHOOL OF MEDICINE

(University of Wales)

DEPARTMENT OF MEDICAL BIOCHEMISTRY

POSTDOCTORAL

RESEARCH OFFICER

required for a D.H.S.S.-funded appointment (renewable annually for up to three years) in the above Department at Heath Park, Cardiff.

The project involves the development of chemiluminescent compounds as alternative labels to radioactive iodine in immunoassay. The aim is to establish clinically useful methods for measuring a variety of peptides and small molecules using luminescence. Candidates should have at least submitted their Ph.D. by time of appointment. Salary on the scales for University Research and Analogous Staff, commencing salary dependent upon qualifications but could be up to £4,302 per annum (under review).

Further particulars (quoting ref. No. C38/4/26) from the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff CF4 4XN to whom applications in the form of a brief curriculum vitae with the names and addresses of two referees should be submitted by April 30, 1979. 405(A)

UNIVERSITY OF BRISTOL

DEPARTMENT OF PATHOLOGY

Applications are invited from veterinary graduates for the post of

LECTURER IN

VETERINARY PATHOLOGY

The person appointed will be responsible primarily for teaching general and special pathology of domestic animals but may also contribute to courses for medical and science students. The Lecturer appointed will be expected to take part in the clinical pathology service to the Veterinary School and to undertake research, for which there are excellent facilities. Experience in teaching and diagnostic veterinary pathology is essential. Salary, which is currently under review, is on an incremental scale within the range £3,883 to £7,754 per annum.

Further particulars may be obtained from the Registrar and Secretary, University of Bristol, Senate House, Bristol BS8 1TH, to whom applications, together with names and addresses of three referees, should be sent by May 7, 1979 (please quote reference EB). 403(A)

UNIVERSITY OF GEZIRA SUDAN

Applications are invited for the following posts in the Preparatory College:—

1. PROFESSOR/ASSOCIATE PROFESSOR/LECTURER IN MATHEMATICS

2. PROFESSOR/ASSOCIATE PROFESSOR/LECTURER IN PHYSICS

3. PROFESSOR/ASSOCIATE PROFESSOR/LECTURER IN PHYSICAL CHEMISTRY

Salary scales: (excluding cost of living allowance) Professor £55,460 per annum; Associate Professor £54,030 to £54,550 per annum; Lecturer £51,500 to £53,500 per annum (£S1 equals £1.25 sterling). The British Government may supplement salaries in range £3,894 to £4,542 per annum (sterling) for married appointees or £1,830 to £2,310 per annum for single appointees (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages; free housing; annual overseas leave. Detailed applications (two copies) with curriculum vitae and naming three referees should be sent by airmail to the Vice-Chancellor, University of Gezira, P.O. Box 2667, Khartoum, Sudan by May 10, 1979. Applicants resident in the UK should also send one copy to Inter-University Council, 90-91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 395(A)

UNIVERSITY OF SYDNEY

LECTURESHIP/SENIOR

LECTURESHIP IN

VETERINARY CLINICAL PATHOLOGY

Appointee to be responsible for teaching, research and diagnostic services in the field of Veterinary Clinical Pathology, will be located in Sydney. Veterinary qualifications or equivalent required. Experience in clinical or practical pathology desirable.

The position may be filled either on a tenured basis, or in the first instance, for a probationary period of three years with the possibility of tenure being given during or shortly after that period.

Salary ranges: Senior Lectureship SA21,180 to SA24,687; Lectureship SA15,786 to SA20,737 per annum.

Applications, including curriculum vitae, list of publications and names of three referees by June 30, 1979 to the Registrar, University of Sydney, N.S.W. 2006, Australia, from whom further information available. Information also available from Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF. 396(A)

ASSISTANT PROFESSOR OF PHYSIOLOGY

The Department of Biology at Clark University invites applications for a tenure track position in physiology. Candidates with postdoctoral experience in cellular, organismal and/or neurophysiology with experience in ultrastructural techniques are preferred. The candidate should be prepared to conduct an independent research programme and teach an introductory physiology course for majors and other appropriate courses at the undergraduate and graduate levels. Deadline date for applications is May 15. Applications should include a curriculum vitae with career objectives and names of at least three referees and be submitted to: Dr V. Ahmadian, Chairman, Biology Department, Clark University, Worcester, MA 01610. Clark University is an Equal Opportunity/Affirmative Action Employer. Applications from women and minorities are encouraged. W45(A)

Experienced Electron Microscopist

An experienced electron microscopist is required in the Special Instrumentation Group of Shell Biosciences Laboratory, Sittingbourne, Kent, to lead a team which provides an expert service for a number of research and development projects pertaining to the life sciences and the agricultural chemical business. The successful applicant will also be expected to conduct his own limited electron microscopy research programme. Current equipment within the electron microscopy team consists of transmission and scanning microscopes, the latter with an X-ray microprobe analysis attachment.

The person we are seeking would probably have a Ph.D. in a biological subject, followed by some years' broad experience in electron microscopy.

We offer a competitive salary and a range of excellent benefits including pension, flexible working hour system, staff restaurant and a recreational club. Please write or telephone for an application form to:

Shell Research Limited, Recruitment Division, (N1) PNEL/11, Shell Centre, London SE1 7NA. Telephone: 01-934 2948.

427(A)

FACULTY POSITION IN NATURAL PRODUCTS CHEMISTRY

DEPARTMENT OF
ENTOMOLOGICAL SCIENCES,
COLLEGE OF NATURAL
RESOURCES
UNIVERSITY OF
CALIFORNIA
Berkeley

Full-time, 11-month research (80 per cent) and teaching (20 per cent) position available in Natural Products Chemistry at the Assistant Professor level. Ph.D. in organic chemistry or other field(s) relevant to natural products required with evidence of interest in chemicals active in insects.

Responsibilities will be in basic and applied research involving bioactive chemicals from insects, plants, and other biological materials that influence insect growth, development, reproduction, and behaviour. Research will include identification and synthesis of active components, and studies on their potential use in managing insect populations. Teaching duties may include developing a course in chemical ecology, environmental chemistry, insect biochemistry, or chemical pest control.

Send full curriculum vitae, official transcripts, copies of significant publications or manuscripts, and names of at least three references by May 1, 1979, to Evert I. Schlinger, Acting Chairman, Department of Entomological Sciences, 137 Giannini Hall, University of California, Berkeley, California 94720. The University of California is an equal opportunity, affirmative action employer.

W47(A)

UNIVERSITY OF SALFORD DEPARTMENT OF BIOLOGY POSTDOCTORAL RESEARCH FELLOW

required for a study of vertebrate respiratory physiology supported by the Agricultural Research Council. Applications are welcome from zoologists and physiologists. Candidates should possess a Ph.D. or expect to gain one in the near future. Informal enquiries may also be made to Dr J. H. Brackenbury, Department of Biology. The post is tenable for up to 3 years.

Salary range: £3,883 to £4,382 per annum (under review), U.S.S. benefits.

Application forms are available from the Registrar, University of Salford, Salford M5 4WT (tel 061-736 5843, ext. 215) to whom completed applications should be returned by Friday, May 11, 1979, quoting reference B/90/N.

423(A)

UNIVERSITY OF LIVERPOOL DEPARTMENT OF ZOOLOGY

Applications are invited for a Lectureship in the Department of Zoology. The successful applicant will assist in the teaching of ecology and will be particularly involved in research and teaching in the freshwater fisheries unit. He will take up his duties on October 1, 1979, or as soon as possible after that date.

The salary will be within the range £3,883 to £4,382 per annum on a scale rising to £7,754 per annum.

Applications, together with the names of three referees, should be received not later than May 14, 1979, by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX from whom further particulars may be obtained. Quote ref. RV/555/N.

407(A)

THE PRINCE HENRY HOSPITAL LITTLE BAY

THE PRINCE OF WALES HOSPITAL RANDWICK

(Teaching Hospitals of the University of New South Wales)

THE EASTERN SUBURBS HOSPITAL BONDI JUNCTION SYDNEY, N.S.W. AUSTRALIA

Applications containing full details of qualifications and experience together with the names and addresses of three referees should be forwarded to:

The Staff Manager,
The Prince Henry, The Prince of Wales,
and The Eastern Suburbs Hospitals,
P.O. Box 233,
MATRIVILLE, N.S.W., 2036, AUSTRALIA

SENIOR STAFF SPECIALIST IN ANATOMICAL PATHOLOGY

with conjoint appointment as

CLINICAL PROFESSOR OR

CLINICAL ASSOCIATE PROFESSOR

SCHOOL OF PATHOLOGY, THE UNIVERSITY OF N.S.W.

Applications are invited from suitably qualified medical practitioners for the above position. The appointee may also be offered the title of Clinical Professor (conjoint appointment) or Clinical Associate Professor (conjoint appointment) and as such would be responsible to the University of New South Wales for teaching in the School of Pathology, with access to the facilities of that school.

The Department of Anatomical Pathology is staffed by three full-time specialists (including the Director) and seven registrars on rotation.

Salary is at a Senior Staff Specialist rate—\$37,850 per annum and appropriate administrative allowance is payable. Conditions in accordance with the Medical Officers Hospital Specialist (State) Award, including three months' paid study leave for each five years of service. Limited right of private practice in accordance with procedures laid down by the Health Commission of New South Wales is also available.

For further information contact Professor A. W. J. Lykke, telephone 662.2770 (Sydney).

Closing date May 28, 1979

W42(A)

UNIVERSITI SAINS MALAYSIA MINDEN, PENANG

APPLICATIONS ARE INVITED for the following vacancies —

- SCHOOL OF PHARMACEUTICAL SCIENCES**
Professor in the fields of PHARMACEUTICAL TECHNOLOGY or PHARMACOLOGY.
Associate Professor in the fields of PHARMACEUTICAL CHEMISTRY, CLINICAL PHARMACY or PHARMACOLOGY.
Lecturer in the fields of PHARMACEUTICAL CHEMISTRY, PHARMACOLOGY, PHARMACEUTICAL TECHNOLOGY or CLINICAL PHARMACY.
- SCHOOL OF APPLIED SCIENCES**
Associate Professor in the fields of ELECTRONIC SCIENCE AND Associate Professor in the fields of ELECTRONIC SCIENCE AND Digital System or Communications; FOOD SCIENCE AND TECHNOLOGY (experience required in Food Processing or Food Manufacture).
- SCHOOL OF BIOLOGICAL SCIENCES**
Professor in the fields of PLANT PATHOLOGY with emphasis on NEMATODES, VIROLOGY or BACTERIOLOGY, AQUATIC BIOLOGY with emphasis on MARINE or FRESHWATER BIOLOGY.
Lecturer in the fields of BOTANY with emphasis on ALGAE, BRIOFITES AND PTERIDOPHYTES, GENERAL MICROBIOLOGY with emphasis on FOOD or ENVIRONMENTAL MICROBIOLOGY.
- SCHOOL OF CHEMICAL SCIENCES**
Lecturer in the fields of PHYSICAL or INORGANIC CHEMISTRY.
- SCHOOL OF MATHEMATICAL SCIENCES**
Professor in the fields of PURE MATHEMATICS (ANALYSIS), APPLIED MATHEMATICS, STATISTICS, COMPUTER SCIENCE or OPERATION RESEARCH.
- SCHOOL OF PHYSICS**
Professor in the fields of EXPLORATION or APPLIED GEOPHYSICS Associate Professor in the field of BIOPHYSICS (RADIATION or MEDICAL BIOPHYSICS)
Lecturer in the fields of EXPLORATION GEOPHYSICS, OCEANOGRAPHY, BIOPHYSICS (RADIATION/MEDICAL BIOPHYSICS), X-RAY CRYSTALLOGRAPHY or SOLID STATE PHYSICS
- SCHOOL OF HOUSING, BUILDING AND PLANNING**
Professor in the field of ENGINEERING (STRUCTURAL & CIVIL).
Lecturer in the field of PLANNING (SOCIAL PLANNING AND DEVELOPMENT, POPULATION PLANNING, MANPOWER & EMPLOYMENT, LANDSCAPING AND ENVIRONMENTAL DESIGN).

QUALIFICATIONS/EMOLUMENTS

Applicants for the post of Professor should be relatively senior in years with a Ph.D. or a Master's degree with a wide and long teaching experience both at undergraduate and postgraduate level. Candidates should also have several outstanding publications to their credit.

Applicants for the post of Associate Professor should have a Master's degree or a Ph.D. with three to five years' experience as a Lecturer. They should be actively engaged in research and should have some research publications to their credit. Experience in supervising higher degree candidates and ability to provide academic leadership is an advantage.

Applicants for the post of Lecturer should have a Master's degree or a Ph.D. with an inclination towards undergraduate teaching and research.

Salary range per annum: Professor, from *M\$35,580 to *M\$40,380, Associate Professor, from *M\$30,300 to *M\$34,380; and Lecturer, from *M\$15,420 to *M\$29,100. Passage assistance, medical benefits and gratuity provided.

Apply to REGISTRAR, UNIVERSITI SAINS MALAYSIA, MINDEN, PENANG, MALAYSIA. Enclose personal vitae and references. The closing date for receipt of applications May 12, 1979.

*Check with your local bank for up-to-date exchange rate. W49(A)

UNIVERSITY OF ST ANDREWS DEPARTMENT OF ASTRONOMY

Applications are invited for a lectureship in the Department of Astronomy tenable from October 1, 1979. Candidates should be experienced observational astronomers with research interests in binary systems and galactic structure. Teaching experience essential.

Salary at appropriate point on scale £3,975 to £8,250 (under review), starting salary probably not above £5,830, plus F.S.S.U./U.S.S.

Applications (two copies preferably in typescript) with the names of three referees should be lodged by April 27, 1979 with the Establishment Officer, The University, College Gate, St Andrews, Fife, from whom further particulars may be obtained. 398(A)

MUSEUM CHEMIST—The Metropolitan Museum of Art, New York City, seeks a young Ph.D. chemist with several years' postdoctoral experience to work in collaboration with the staff of the Paintings Conservation Department. The applicant should be conversant with the following techniques: X-ray diffraction; gas chromatography; mass spectrophotometry; electrophoresis; radio-amino assay and wet chemical analysis. Responsibilities will include the identification and testing of materials, particularly organic, that have been used in the fabrication and treatment of paintings of all periods as well as long term research projects. Some knowledge and interest in paintings as works of art is essential. The candidate must be flexible and practical and willing to work outside one area of expertise. Forward application to: Mr. John M. Brealey, Conservator, Metropolitan Museum of Art, Fifth Avenue and 82nd Street, New York, New York 10028. W54(A)

FACULTY POSITION IN INSECT PATHOLOGY DEPARTMENT OF ENTOMOLOGICAL SCIENCES, COLLEGE OF NATURAL RESOURCES UNIVERSITY OF CALIFORNIA Berkeley

Full-time, 11-month research (75 per cent) and teaching (25 per cent) position available in insect pathology at the Assistant Professor level available July 1, 1979. Expertise mandatory in one of the following areas: bacteriology, comparative virology, mycology, or protozoology. Ph.D. and background in pathology required and post-doctoral experience desirable.

Responsibilities will be in basic and applied research and teaching in insect pathology and pest management. Experience in pathogen-insect relationships, pathogenicity, and the manipulation of pathogens for insect control will be weighting factors when judging applicants.

Send full curriculum vitae, official transcripts, copies of significant publications or manuscripts, and names of three references by May 1, 1979, to Evert I. Schlinger, Acting Chairman, Department of Entomological Sciences, 137 Giannini Hall, University of California, Berkeley, California 94720. The University of California is an equal opportunity, affirmative action employer. W46(A)

UNIVERSITY OF NAIROBI KENYA

Applications are invited for the post of

ASSOCIATE PROFESSOR IN DEPARTMENT OF BIOCHEMISTRY

Applicants must have a Ph.D. or equivalent in Biochemistry and have research and teaching experience at University level. The appointee will be required to teach biochemistry to the undergraduate students in the faculties of Medicine, Science, Veterinary Medicine and Agriculture. He/she will also be required to supervise M.Sc. and Ph.D. students and at the same time pursue their own research projects in biochemistry. Salary scale KES 864 to KES 4,488 per annum (KEI equals £1.30 sterling). The British Government may supplement salary by £5,784 per annum (sterling) for married appointee or £3,876 per annum (sterling) for single appointee (currently under review and normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages, superannuation scheme, medical aid scheme; subsidised housing, various allowances. Detailed applications (two copies) with curriculum vitae and naming three referees should be sent by air mail to Registrar, University of Nairobi, P.O. Box 30197, Nairobi, Kenya by May 29, 1979. Applicants resident in the UK should send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 415(A)

HARVARD MEDICAL SCHOOL NEUROBIOLOGIST

The Department of Neurobiology is seeking a new faculty member at the assistant-professor level to begin 1979 or 1980. Applications from women and minority people are encouraged. Please send curriculum vitae and a brief outline of research plans, and have three letters of reference sent to

Search Committee
Department of Neurobiology
Harvard Medical School
25 Shattuck Street
Boston MA 02115

W52(A)

THE HANNAH RESEARCH INSTITUTE FOR STUDIES RELATING TO THE PRODUCTION AND UTILISATION OF MILK METABOLIC PHYSIOLOGIST

A vacancy exists for a Higher Scientific Officer in the Physiology Department to study metabolism in goats and cows in relation to the control of milk secretion and to nutritional and environmental factors.

Applicants should possess a First or Upper Second Class Honours Degree in a relevant discipline with, preferably, a Ph.D.

Salary will be in the range £4,101 to £5,448. At least two years' relevant postgraduate experience is required for appointment to HSO. Non-contributory pension scheme in operation.

Further particulars may be obtained from

The Secretary
The Hannah Research Institute
AYR KA6 5HL

to whom applications, which should include a curriculum vitae, list of publications, and the names and addresses of three referees, should be sent by: April 20, 1979. 387(A)

MCGILL UNIVERSITY DEPARTMENT OF BIOLOGY

PCSTDOCTORAL FELLOW

Required to work in a project on the interaction of the killer toxin protein with cell surface receptors in yeast. Experience in protein chemistry and/or yeast genetics an advantage. The appointment is for one year initially and may be renewed for a further two years. Initial salary \$13,000 per annum. Applications and two letters of recommendation should be sent to Dr H. Bussey, Department of Biology, McGill University, 1205 Avenue Docteur Penfield, Montreal, Quebec, Canada, H3A 1B1. W50(A)

THE POLYTECHNIC OF NORTH LONDON DEPARTMENT OF FOOD SCIENCES Applications are invited for the following post: **TEMPORARY LECTURER II IN NUTRITIONAL BIOCHEMISTRY** for an initial period of one year from 1st September 1979 with a possible extension for a further year. The Lecturer will be required to teach and supervise projects at both degree and diploma level. The main biochemical teaching is required for the 18 month Diploma in Dietetics course but the Lecturer will play an important part in integrating the teaching of biochemistry with the nutrition taught at degree level. Applicants should hold a degree in which biochemistry in relation to man was a major area of study, and must be able to relate their teaching to the field of human nutrition. Experience in teaching would be an advantage. Salary Scale: £4,575 to £7,032 (including London Allowance). Application form and further particulars from the Establishment Officer, The Polytechnic of North London, Holloway Road, N7 8DB. Tel. 01-607 2789, Ext. 2018. Closing date—two weeks from the appearance of this advertisement. 406(A)

TWO postdoctoral positions are available immediately to study the structural organization of the nitrogen fixing gene cluster of *Klebsiella*. One additional position will be available starting July 1, to clone plant DNA in E. coli and in yeast. Requirement: Ph.D. in biochemistry or in molecular biology. Candidates with research experience in phage, viral, or plasmid systems preferred. Send curriculum vitae and two references to: Dr A. A. Szalay Boyce Thompson Institute at Cornell University, Tower Road, Ithaca N.Y. 14853. W56(A)

THE UNIVERSITY
OF LEEDS
DEPARTMENT OF
PHYSIOLOGY

Applications are invited for a temporary post of RESEARCH FELLOW in the above Department. The successful candidate will work with Professor B. R. Jewell in a small team with interests in various aspects of cardiac muscle physiology. Candidates should possess a Ph.D. degree in Physiology and Biochemistry. The appointment will be made for a fixed period of three years.

Salary at an appropriate point on the LA scale for Research and Analogous Staff (£3,883 to £6,555) (under review), according to age, qualifications and experience.

Informal enquiries about the post may be made to Professor Jewell (telephone (0532) 31751, ext 7267).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 104/7/D. Closing date for applications May 25, 1979.

401(A)

UNIVERSITY OF
EDINBURGH
FACULTY OF MEDICINE
LECTURESHIP IN
PHYSIOLOGY

Applicants must have a good Honours degree in Physiology and at least three years' research experience. Salary on the scale £3,883 to £7,754 per annum (under review).

Further particulars may be obtained from the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh EH8 9YL, with whom applications (6 copies) including a full curriculum vitae and the names and addresses of three referees should be lodged not later than May 18, 1979.

Please quote Reference 1035.

399(A)

UNIVERSITY OF READING
DEPARTMENT OF PHYSIOLOGY
AND BIOCHEMISTRY

Applications are invited for a Lectureship, for a fixed term of one year beginning on October 1, 1979. The Department teaches Physiology, Biochemistry and Nutrition in the Faculty of Science and in the Faculty of Agriculture and Food. Applicants should hold a good honours degree in an appropriate subject and have experience of research and preferably of teaching. The person appointed would be expected to join in the research activities of one of the established groups in the Department.

The appointment will be in the Lecturers' salary scale within the range £3,883 to £4,882 (under review).

Further information may be obtained from the Registrar, (Room 214, Whiteknights House), The University, Whiteknights, Reading RG6 2AH, to whom applications should be received not later than May 26, 1979.

406(A)

UNIVERSITY OF BATH
Applications are invited for a
LECTURER
IN BIOCHEMISTRY

The starting salary will be set in the lower part of the salary range £3,883 to £7,754 per annum.

Further particulars and application forms obtainable from the Personnel Officer, University of Bath, Bath BA2 7AY, quoting reference number 79/70/N.

Closing date for applications May 14, 1979.

379(A)

Medical Development Project Co-ordinators

May & Baker is an international Company, manufacturing and marketing a wide range of research based pharmaceuticals.

In connection with the internal expansion of our pharmaceutical development organisation, we have created vacancies for Medical Development Project Co-ordinators. These are key posts carrying responsibility for the planning and progress of the development of new medical specialty products. The work involves close liaison with senior staff in all areas of R & D.

Candidates should possess a good honours degree in a biological science or chemistry and an ability to communicate clearly in discussions and in written reports. Preference will be given to those applicants with experience in the pharmaceutical industry, particularly in the field of medical product development. Familiarity with modern project planning techniques and a working knowledge of the French language would be an advantage.

Benefits of employment include competitive salaries, flexible working hours, subsidised meals and a contributory pension scheme with life assurance. Assistance with relocation expenses will be given where appropriate.

Please telephone 01-592 3060 extension 2506 for an application form or write with full details of career to date to

M&B May & Baker

Mrs. P. Clark, Personnel Officer,
May & Baker Ltd, Dagenham, Essex RA10 7XS
quoting reference number 120 N 1.

430(A)

IMPERIAL COLLEGE OF
SCIENCE AND
TECHNOLOGY
CENTRE FOR
ENVIRONMENTAL TECHNOLOGY
Mathematical Models of the
Population Biology of Human
Infectious Diseases in
Urban Environments

Applications are invited for a Postdoctoral Research Post in the Centre for Environmental Technology as part of a contract from the Department of the Environment.

The work involves dynamic modelling of the population biology of infectious diseases (measles, mumps, whooping cough and sexually transmitted diseases) with particular reference to human density and other environmental parameters in urban settings.

Candidates should preferably possess a Ph.D. in applied mathematics of mathematical ecology with ideally experience of epidemiological work.

The appointment will be for a period of two years in the first instance. Salary will be on scale 1A, £3,883 to £6,555 per annum (under review), plus London Allowance.

Applications including curriculum vitae and names of two referees should be sent to Dr R. M. Anderson, Centre for Environmental Technology, Imperial College of Science and Technology, London SW7 2AZ by June 1, 1979.

392(A)

A faculty position is available for an individual with a Ph.D. in Physiology and demonstrable training with scientific accomplishments in the area of smooth muscle electrophysiology, mechanics and/or biochemistry. Only those who meet these qualifications should send a curriculum vitae and selected reprints to: Dr Stanley G. Schultz, Professor and Chairman, Department of Physiology, University of Texas Medical School at Houston, P.O. Box 20708, Houston, Texas 77025 (An Equal Employment Opportunity, Affirmative Action Employer) W57(A).

SEVERAL junior and senior faculty positions are available for individuals with Ph.D.'s in Physiology and demonstrable scientific accomplishments in the areas of ion transport and electrophysiology of epithelial tissues; a familiarity with computer sciences is also desirable. Only those who meet these qualifications should apply. A curriculum vitae and selected reprints should be forwarded to: Dr Stanley G. Schultz, Professor and Chairman, Department of Physiology, University of Texas Medical School at Houston, P.O. Box 20708, Houston, Texas 77025, (An Equal Employment Opportunity, Affirmative Action Employer) W58(A).

M.R.C. CLINICAL RESEARCH CENTRE
(Northwick Park Hospital)

Watford Road, Harrow, Middlesex HA1 3UJ

KERATIN PROTEIN CHEMIST

required to join Dermatological Group with special interest in collagen chemistry and related diseases.

The appointee should develop methods of keratin protein separation which would allow of certain inherited and acquired epidermal diseases at a molecular level.

This is a limited term appointment for four to five years depending on age and experience.

Salary within the range £5,367 to £7,754 plus £450 London Allowance.

Application form and further details obtainable from Mrs J. Tucker-Bull. Please quote reference 110/1/4178. Closing date April 23, 1979.

431(A)

The Research Organisation of an Internationally recognised European Pharmaceutical Group located in Paris requires a

TECHNICAL RESEARCH OFFICER

The high success rate and rapid growth of this pharmaceutical group is related to the quality of people they employ and their continued commitment to research and development

To strengthen the research effort. The research organisation requires a professional and highly motivated scientist who will be responsible for:

- Advising on the implementation of the GLP standards within research and within a proposed new research centre.
- Assisting with the planning and organisation of research projects.
- Organising the collation and storage of research data.

Applicants can be either male or female and should be a graduate in the biological sciences. It is essential that the candidate should have experience of the pharmaceutical industry.

A realistic salary can be expected and relocation assistance will be available together with other financial benefits.

All applications will be treated in the strictest confidence and should be sent to 'Nature', c/o Box No. W53(A), 3 Dyers Building, Holborn, London EC1N 2NR. W53(A)

THE UNIVERSITY OF LEEDS DEPARTMENT OF PHYSIOLOGY

Applications are invited for a temporary post of LECTURER in the above Department, tenable from October 1, 1979 for a fixed period of three years. The Department teaches Science, Medical and Dental students, and has research interests in the major fields of physiology.

Salary on the scale for lecturers £3,883 to £7,754 (under review), according to age, qualifications and experience.

Informal enquiries to Professor B. R. Jewell, Department of Physiology (telephone 0532) 3175, ext. 7267.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 104/6/D. Closing date for applications May 7, 1979.

402(A)

UNIVERSITY COLLEGE LONDON DEPARTMENT OF CHEMISTRY POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a position as postdoctoral research assistant to work with Dr B. P. Roberts on ESR, and chemical studies of nitrogen-, oxygen-, and sulphur-centered free radicals. An appreciable amount of synthetic organic chemistry will be involved. Appointment for two years, starting from October 1979 (earlier starting dates are possible). Starting salary in range £3,909 to £4,408 per annum, plus £502 London Allowance, depending on age and experience. Applications, including curriculum vitae and names and addresses of two referees to Dr B. P. Roberts, Department of Chemistry, University College London, 20 Gordon Street, London WC1H 0AJ. 375(A)

IMPERIAL COLLEGE DEPARTMENT OF CIVIL ENGINEERING LECTURER IN SOIL MECHANICS

Applications are invited for the post of Lecturer in soil mechanics. The soil mechanics section is linked, under the general heading of geo-technical engineering, with groups specialising in engineering rock mechanics, engineering geology and engineering seismology.

The section runs a large M.Sc. course, as well as being involved in undergraduate teaching and a wide variety of experimental and theoretical research. It also forms part of the S.R.C.-sponsored London Centre for marine structures and materials.

The Lecturer will be involved in both undergraduate and postgraduate teaching, and will be expected to play an active part in the conduct and supervision of research.

Applicants with varying practical experience and a variety of specialisms at research level will be considered, although a knowledge of numerical methods and/or dynamic problems would be of particular interest. Subject to suitable postgraduate experience, applicants need not have a first degree in civil engineering.

Salary is the scale £3,883 to £7,754 per annum plus London Allowance.

Applications and enquiries should be made to Professor B. G. Noel, Head of Civil Engineering Department, Imperial College, South Kensington, London SW7 2AZ. 391(A)

PLANT TISSUE CULTURE DEPARTMENT OF MICROBIOLOGY AND CELL SCIENCE UNIVERSITY OF FLORIDA

Applications are invited for a tenure track faculty position currently open at the ASSISTANT PROFESSOR rank for individuals with a Ph.D. and demonstrated expertise in plant tissue culture. Individuals working in the areas of biochemical genetics and molecular biology are particularly solicited.

Responsibilities will include development of a vigorous research program utilising plant tissue culture techniques to explore molecular and subcellular phenomena involved in plant development. After the program becomes established, part of the responsibility will be to provide advice and consultation to other scientists in the general area of plant tissue culture.

Applicants should submit curriculum vitae, a statement describing current research activities and detailing future plans, and at least three letters of recommendation to:

Dr Paul H. Smith, Chairman
Department of Microbiology
and Cell Science
1059 McCarthy Hall
University of Florida
Gainesville, Florida 32611

The University of Florida is an Equal Opportunity and Affirmative Action Employer. W41(A)

CAMBRIDGE UNIVERSITY DEPARTMENT OF GENETICS Applications are invited for an ASSISTANT TECHNICAL OFFICER

to be responsible for the organising of the maintenance of Drosophila.

The scale of stipends, for a person not normally resident in College, is at present £3,634 per annum, at age 23, rising by annual increments to £5,367.

Applications, with the names of not more than three referees, should be sent to the Secretary of the Appointment Committee of the Faculty of Biology "A", Department of Applied Biology, Pembroke Street, Cambridge CB2 3DX, from whom further particulars may be obtained. Applications should reach him by not later than May 12, 1979. 385(A)

MONASH UNIVERSITY Melbourne, Australia DEPARTMENT OF CHEMISTRY JUNIOR RESEARCH FELLOW (THEORETICAL CHEMISTRY)

To undertake theoretical investigations into the Auger electron spectra of small molecules with Dr F. P. Larkins for a period of two years subject to a satisfactory review one year from the date of appointment. The successful candidate should have a Ph.D. degree or equivalent qualifications with a strong background in theoretical chemistry or physics. A sound knowledge of molecular orbital theory would be advantageous. A salary in the range \$A13,083 to \$A14,606 per annum is offered with some provision for travel costs. Applications including three referees and curriculum vitae to the Academic Registrar, Monash University, Wellington Road, Clayton, Victoria, Australia, 3168. Further details available from Dr Larkins. Applicants should quote reference No. 41061. Closing date April 30, 1979. 389(A)

UNIVERSITY OF EDINBURGH DEPARTMENT OF ZOOLOGY

Applications are invited for the post of Lecturer in the Department of Zoology. Salary scale £3,883 to £7,754 per annum (under review), with placement according to qualification and age, and with superannuation benefit.

The successful candidate will be expected to take up duty on October 1, 1979.

Further particulars may be obtained from the Secretary to the University of Edinburgh, Old College South Bridge, Edinburgh, with whom applications (six copies), giving the names of two referees, should be lodged not later than May 5, 1979. Please quote Reference 1032. 400(A)

PROFESSORSHIP IN MOLECULAR GENETICS

Seeking individual for Professorship in Molecular Genetics. Individual must be established investigator for research and teaching in molecular genetics.

Position in Cancer Center with broad laboratory research programmes including cellular genetics and development, tumour immunology, virus oncology, and chemical carcinogenesis.

Salary negotiable dependent on level of experience and academic rank of applicant. Send curriculum vitae and inquiries to: Chairman, Molecular Genetics Professor Search Committee Cancer Center/Institute of Cancer Research, Columbia University, 701 West 168th Street, New York, New York 10032.

An Equal Opportunity Employer. W60(A)

TECHNICIAN/RESEARCH OFFICER

required for Tumour Virology Laboratory, for work involving tissue culture (preparation of primary cultures and handling of normal and virus-infected cell lines), virus assays, cytological techniques (cell-fusion, karyology) and nucleic acid biochemistry (DNA extraction, enzyme assays, hybridisation). The technician will share routine laboratory duties but would also work on research projects without day-to-day supervision.

Degree/HNC required plus at least two years relevant laboratory experience. Salary range £3,582 to £4,902 plus L.W. Appointment available May 1979. For application form write or telephone Miss S. M. Hurley, Imperial Cancer Research Fund, Lincoln's Inn Fields, WC2 on 01-242 0200 ext. 305. 412(A)

Avon Area Health Authority (T. —Southmead Health District SOUTHMEAD HOSPITAL BRISTOL RESEARCH ASSISTANT

Research Assistant required for a 3 year supervised project to study alterations in cell membrane glycoproteins, surface charges and enzyme cytochemistry in human leukaemia. Some tissue culture work will also be carried out.

Applicants should possess an honour degree in Biochemistry or related subject. The post is available from June 1, 1979. Salary range: £3,486 to £4,275.

Applications to and further details from Dr I. D. Fraser, Department of Haematology, Southmead Hospital Bristol BS10 5NB Tel: Bristol (0272) 505050 by April 30, 1979. 404(A)

EDITORIAL SERVICES CONTROLLER

We need an experienced, literate and adaptable Editorial Controller to work in our Higher and Further Education division, managing a wide variety of typescripts in subjects ranging from undergraduate science to semi-technical hobbies. The job involves working closely with the Further Education, Published, copy-editing and proof-reading, as well as dealing with authors, freelance staff, and our own production staff. Accuracy, and the ability to rewrite where necessary are important. Training will be provided for a person with the required academic and work record.

We are based at Basingstoke, close to the M3. The right person will be offered a competitive salary, and will be entitled to 20 days' holiday per year. We also have a subsidised bar, canteen, social club, pension scheme, and free transport to and from the town centre.

Send your application in handwriting, along with a detailed curriculum vitae, to: **Sheilagh Browne, Personnel Manager, The Macmillan Press Ltd., 4 Little Essex Street, London WC2R 3LF.** 333(A)

**M MACMILLAN
PRESS**

UNIVERSITY OF YORK CANCER RESEARCH UNIT RESEARCH ASSISTANT

Applications are invited for the above post in the Cancer Research Unit, which is shortly moving into new laboratories. The post is suitable for someone who has, or expects to have, an honours degree in Biochemistry or Biology, preferably with some microbiological experience.

The appointment will be made as soon as possible and is for a two-year period. The research work will involve the study of microbiological methods of detecting reactive metabolites of chemical carcinogens.

Further information concerning the work may be obtained from Dr R. C. Garner (Tel. York (0904) 31805).

Salary will be on the Range 1B, starting at £3,384, currently under review.

Four copies of applications, naming two referees, should be sent by May 4, 1979, to the Registrar, University of York, Heslington, York YO1 5DD. Please quote reference number 11/7078. 424(A)

THE UNIVERSITY OF MANCHESTER RESEARCH ASSOCIATE IN PATHOLOGY

Applications invited for this post, tenable for three years from a date to be arranged. The project is to investigate the nature and significance of intraduct proliferative breast lesions and their relationship to carcinoma in humans. A variety of techniques will be employed including electron microscopy, microdensitometry and immunofluorescence. Initial salary range per annum: £3,883 to £4,382. Superannuation. Applications (curriculum vitae and three referees) should be sent to the Registrar, The University, Manchester M13 9PL by April 30. Quote Ref: 75/79. Further information from Dr M. Harris, Department of Pathology, University Hospital of South Manchester, Manchester M20 8LR (Tel: 061-445 8111, Ext. 2760). 409(A)

THE POLYTECHNIC OF NORTH LONDON SCIENCE AND TECHNOLOGY FACULTY RESEARCH ASSISTANT

required to (a) assist in the development and teaching of a new course "Science and the Making of the Modern World" taken by all students on the B.Sc. Science degree; the course surveys developments in science since the 17th century and outlines some of the ways in which science has shaped the modern world; (b) conduct research—for a higher degree, if appropriate—on some topic in the history and/or social aspects of science which is relevant to the above course. The post is tenable for one year in the first instance, renewable for up to three years. Salary Scale: £3,087 to £3,261 (including London Allowance). A good first degree in Natural Science or covering the historical, philosophical or social aspects of science is required; some teaching experience an advantage. Further particulars are available from Dr J. Marks, Physics Department, The Polytechnic of North London, Holloway Road, N7 8DB. 377(A)

UNIVERSITY OF OTAGO Dunedin, New Zealand LECTURER IN ZOOLOGY AND MARINE SCIENCE

Applications are invited for the position of Lecturer in Zoology and Marine Science. This position is a joint appointment between the Department of Zoology and the Portobello Marine Laboratory, and the person appointed will be expected to contribute to the teaching programme of the Department of Zoology and to devote approximately half his time to research and other duties at the Marine Laboratory. Some preference may be shown towards candidates whose research interests are in marine field of studies which utilise the resources of the sea-going research vessel of the Marine Laboratory.

Salary Scale—NZ\$11,894 to NZ\$14,615 per annum. Further information is available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University. Applications close on June 15, 1979. 388(A)

Microbiologist

G. D. Searle is a leading Pharmaceutical company with its main U.K. site and Research laboratories at High Wycombe in Buckinghamshire.

Within the laboratories we are involved in a growing number of research and development programmes in various fields of medical science.

The position of Microbiologist would ideally suit an experienced man or woman who would join the Research and Development Division to take on responsibility for several branches of microbiological work, primarily the monitoring of sterile production and testing facilities, but also providing microbiological advice for programmes on fermentation development and microbiological research. The person appointed will report to the Biological Quality Control Manager.

Candidates should have several years' experience in this field, probably with a PhD and possibly with specific experience of microbiological aspects of tissue culture based vaccine production. All applicants should have at least a working knowledge of GMP requirements and should enjoy a real challenge – with the potential satisfaction of making significant advances in the world of medicine.

In addition to a competitive salary, conditions of employment include 4 weeks' holiday per year, a contributory pension fund, subsidised private health insurance, sports and social club and staff cafeteria.

Applications are requested, quoting reference M/R16, either in writing, giving career details, or by telephoning for an application form to: G. Jenkins, Personnel Manager, Research & Development, G. D. Searle & Co. Ltd., Lane End Road, High Wycombe, Bucks. (Tel. High Wycombe 21124 ext. 3374).

SEARLE

THE DISTILLERS COMPANY LIMITED Yeast and Food Division MICROBIAL BIOCHEMIST

The Yeast and Food Division of The Distillers Company Limited require a graduate to work in areas of Microbial Biochemistry in their research and development laboratories, Glenochil Technical Centre, Menstrie, Clackmannanshire.

Applicants, who should be under 28 years old, must have a degree in microbiology, biochemistry or closely related subjects and preferably have postgraduate experience.

Further details together with an application form can be obtained by writing to: The Yeast Research Manager, The Distillers Company Limited, Yeast and Food Division, Glenochil Technical Centre, MENSTRIE, Clackmannanshire FK11 7ES. 305(A)

FELLOWSHIPS

OXFORD UNIVERSITY
and ICI JOINT RESEARCH
SCHEMEResearch
Fellowship

Applications are invited for a Joint Research Fellowship, to work on the THEORETICAL INVESTIGATION OF SOLVENT EFFECTS, to be held in the Physical Chemistry Laboratory, Oxford University.

The proposal is to study the effects of water on solutes by statistical mechanical methods allied with quantum mechanical calculations. The work will be carried out in Oxford and in collaboration with Dr K J Heritage, ICI Plant Protection Division, Jealott's Hill Research Station, Bracknell, Berkshire.

The Fellowship will be tenable for two years at a starting salary of up to £4,382 (under review) with membership of USS.

Applications with curriculum vitae and the names of two referees should be sent to Dr W G Richards, Physical Chemistry Laboratory, South Parks Road, Oxford, OX1 3QZ. 382(E)

Plant Protection
Division

POSTDOCTORAL
FELLOWSHIPS:
MEDICAL

OR

Ph D. GRADUATES

The School of Pathology of the South African Institute for Medical Research and the University of the Witwatersrand offers one-year fellowships (renewable) for scientists interested in working in any of the following fields:—

- Histopathology
- Haematology and/or Immunohaematology
- Medical Biochemistry
- Microbiology
- Tropical Pathology (including parasitology)
- Vaccine Production
- Mycology
- Cytology
- Human Genetics (including cytogenetics)
- Immunology
- Epidemiology
- Electron Microscopy

Clinical material and laboratory facilities are available for research in these fields. The fellowships will provide opportunity for challenging research in diseases of importance for developing countries.

For further details contact —

Head, Personnel Services, The South African Institute for Medical Research, P O Box 1038, Johannesburg 2000, South Africa. Tel 724-1781. W48(E)

POSTDOCTORAL
FELLOWSHIP

A postdoctoral fellowship is open for work on the structure and dynamics of fluids with the neutron scattering group at the University of Guelph. Present projects include the study of three body forces and correlations in atomic gases and molecular orientation effects in molecular gases. Duties include participation in neutron scattering experiments (for extended periods) at A.E.C.L., Chalk River and (for short periods) at I.L.L., Grenoble, France. This position will be open until filled. Initial appointment for one year with renewal for a second year by mutual agreement. Salary approximately \$12,000 per year. Candidates with Ph.D. in any area of condensed matter or nuclear physics will be considered, and should send C.V. and names of two referees to: Dr P A. Egelstaff, Department of Physics, University of Guelph, Guelph, Ontario, Canada N1G 2W1. W43(E)

UNIVERSITY OF BRISTOL
SCHOOL OF CHEMISTRY
POSTDOCTORAL
FELLOWSHIP IN
LASER SPECTROSCOPY

Applications are invited for a Postdoctoral Research Fellowship for two years from October 1, 1979, to work on the infrared spectroscopy of unstable molecules and free radicals. The project will make use of modulated CO₂ lasers in conjunction with Stark and Zeeman tuned absorption cells, and will be oriented to problems of astrophysical importance.

The post is S.R.C. funded, and the initial salary will be in the range £3,883 to £4,382 per annum (scale under review).

Applicants should send a curriculum vitae and the names of two referees to: Dr Geoffrey Duxbury, School of Chemistry, The University, Bristol BS8 1TS, U.K. 419(E)

BRANDEIS UNIVERSITY
Rosenstiel Center

A postdoctoral fellowship is available for the study of structure and assembly of tobacco mosaic virus by X-ray diffraction from oriented gels. Extension and refinement of present 4 Å structure, study of other helical TMV protein aggregates and of related viruses. Project is related to larger program of Dr D L. D Casper on virus structure. Computing ability is desirable and preferably crystallography, protein chemistry or biological structure experience. Available immediately, for up to two years. \$12,500–\$15,000.

Contact Dr G Stubbs, Rosenstiel Center, Brandeis University, Waltham, MA. 02154, USA (617)-647-2467. W55(E)

ASSISTANTSHIPS

UNIVERSITY OF
ST. ANDREWS
DEPARTMENT OF
APPLIED MATHEMATICS
POSTDOCTORAL
RESEARCH
ASSISTANTSHIP

Applications are invited for a position as Research Assistant, from October 1979, to work with Dr B Roberts on the theoretical nature of solar intense magnetic fields. The programme will involve the development of theories for spicules (transient flows in a magnetic tube) and for the propagation of waves in intense tubes. Links with the observations may be maintained by visiting Kitt Peak and Sacramento Peak Observatories. Ideally, applicants should have a Ph.D. in Applied Mathematics or Theoretical Physics.

The appointment is supported by S.R.C. and is initially for one year with good prospects for an extension to two or three years. Starting salary will be in the range £3,975 to £4,505 (under review).

Applications should be lodged by May 4, 1979, with Dr B. Roberts, Department of Applied Mathematics, University of St. Andrews, Fife, from whom further particulars may be obtained (Tel: St Andrews 74317). 422(P)

UNIVERSITY OF DURHAM
DEPARTMENT OF PHYSICS

Applications are invited from an electronics engineer or physicist with an electronics background for a senior research assistantship, tenable for two years, from as soon as possible. The work will involve the development of silicon diode arrays for low light level imaging in astronomy and their associated data acquisition systems. Experience with minicomputer systems would be an advantage.

Initial salary in the range £3,883 to £5,129 (under review) on range 1A plus superannuation.

Applications (three copies) naming three referees should be sent by May 11, 1979 to the registrar and secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. 410(A)

UNIVERSITY OF DURHAM
DEPARTMENT OF PHYSICS
POSTDOCTORAL
SENIOR
RESEARCH ASSISTANTSHIP

tenable for three years from 1st October, 1979. The successful applicant will participate in a new research project devoted to the theoretical study of low energy molecular collisions.

Initial salary in the range £3,883 to 4,917 (plus superannuation).

Applications (three copies) naming three referees should be sent by April 30, 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. 280(P)

UNIVERSITY OF DURHAM
DEPARTMENT OF
CHEMISTRY

Applications are invited from chemists, materials or polymer scientists, or solid state physicists for an S.R.C. funded postdoctoral Senior Research Assistantship tenable for two years from October 1, 1979 (or earlier by arrangement) for an interdisciplinary investigation of the formation and properties of thin films and of structure and reactivity of polymeric systems, and composites in general, primarily by E.S.C.A. The appointee will assist in setting up a custom designed spectrometer dedicated to the research.

Salary £3,883 to £4,133 on range 1A plus superannuation.

Applications (three copies) naming three referees should be sent by June 1, 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. 411(P)

STUDENTSIPS

UNIVERSITY OF
EDINBURGH
RESEARCH STUDENTSHIP

Applications are invited for a Medical Research Council Studentship to investigate various biochemical and immunological methods for detecting carriers and pre-clinical cases of muscular dystrophy.

Applicants should have, or be likely to graduate with, at least an Upper Second-Class Honours Degree in a relevant field and will be expected to register for a higher degree.

Please send C.V. and the names of two referees to:

Professor A. E. H. Emery,
University Department of Human Genetics,
Western General Hospital,
Edinburgh EH4 2XU. 421(F)

UNIVERSITY OF LONDON
REACTOR CENTRE
(Ascot, Berkshire)

POSTGRADUATE RESEARCH

The Science Research Council is preparing this year to offer suitable candidates a limited number of Research Studentships, tenable at the University of London Reactor Centre. The Reactor Centre, operated for the University by Imperial College, provides facilities and supervision for students to engage in research leading to the degrees of M.Phil. and Ph.D. of the University of London.

Current fields of research include low energy nuclear physics, neutron activation analysis, radiochemistry and reactor physics.

Applicants holding, or expecting to obtain in 1979, a good honours degree in a physical science, can obtain further information and an application form by writing to: The Registrar, Imperial College of Science and Technology, London SW7 2AZ. 374(A)

THE UNIVERSITY
OF LEEDS
DEPARTMENT OF
PLANT SCIENCES
M.A.F.F.
POSTGRADUATE
AGRICULTURAL
STUDENTSHIP

Applications are invited for a postgraduate studentship for research on techniques for the inoculation of field crops with vesicular-arbuscular mycorrhizal fungi.

A first or upper-second class Honours degree is essential.

Application (before end of May) and enquiries to: Dr F. E. Sanders, Department of Plant Sciences, Agricultural Sciences Building, University of Leeds, Leeds LS2 9JT. 384(F)

STUDENTSHIPS—continued

THE OPEN
UNIVERSITYBRAIN
RESEARCH GROUPResearch
Studentships

Ph.D. studentships are available in the Open University Brain Research Group, (Head, Professor Steven Rose) for graduates with good biochemistry/cell biology degrees to work on projects in the area of developmental neurobiology and biochemical and cellular correlates of experience and learning.

Further particulars and application forms are available from the Higher Degrees Office, The Open University, P.O. Box 49, Milton Keynes, MK7 6AD. Please quote reference (RR/9). The closing date for receipt of applications is 26th April. 373(F)

UNIVERSITY OF
NOTTINGHAM
FACULTY OF
AGRICULTURAL SCIENCE
POSTGRADUATE
STUDENTSIPS

Applications are invited for Ph.D. studentships in the Department of Physiology and Environmental Studies for research in the following fields:—

(i) Interactions between endocrine status and sexual behaviour in the ram.

(ii) Endocrine control of mammary gland metabolism (including cardiovascular parameters) in lactating ruminants.

Applicants should possess, or expect to obtain this summer, a first class or upper second class Honours degree in an appropriate subject.

Further details may be obtained from the Secretary, University of Nottingham, Faculty of Agricultural Science, Sutton Bonington, Loughborough, Leics. LE12 5RD, to whom completed applications including a full curriculum vitae and names and addresses of two referees should be sent by April 30, 1979. 381(F)

UNIVERSITY OF
LEICESTER
DEPARTMENT OF BOTANY
N.E.R.C.
RESEARCH STUDENTSHIP

Applications are invited from graduates, or those expecting to graduate this summer, for a N.E.R.C. Research Studentship. The Studentship is available for one only of the following research projects:

(1) Effect of real and simulated vegetation canopies on the maturation and subsequent germinability of weed seeds.

(Supervisor: Professor H. Smith)

(2) Available genetic resources of turf grasses—C.A.S.E. studentship with the Sports Turf Research Institute.

(Supervisor: Dr C. A. Stace)

The first project will be of interest to a plant physiologist/ecologist whereas the second project would be more suited to a plant taxonomist. All promising candidates will be invited to the Department for informal discussions.

Requests for further information and applications should be addressed to Professor H. Smith, Department of Botany, University of Leicester, Leicester LE1 7RH. 313(F)

UNIVERSITY OF
WARWICKC.A.S.E. STUDENTSHIP
KINETICS OF DIAZONIUM
SALT REACTIONS BY FAST
REACTION METHODS

Applications are invited for a three-year S.R.C. (C.A.S.E.) Research Studentship in the Department of Chemistry and Molecular Sciences, starting October 1, 1979, and supervised by Dr T. J. Kemp in collaboration with Dr J. Atherton (ICI Organics). The programme will involve a kinetic study of the decomposition and coupling reactions of ArN_2^+ ions using stopped-flow spectrophotometry combined with a rapid-scanning spectrometer which provides complete u.v.-visible spectra in milliseconds. Applicants should hold or expect to hold at least an upper second class honours degree in chemistry. Further details may be obtained from Dr Kemp, Department of Chemistry and Molecular Sciences. Applications with the names of two referees should be sent as soon as possible to the Academic Registrar, University of Warwick, Coventry CV4 7AL. Please quote Ref. No.: PG/41/79. 383(F)

UNIVERSITY OF LONDON
REACTOR CENTRE
S.R.C. C.A.S.E. STUDENTSHIP

Applications are invited for a Research Studentship tenable for three years at the University of London Reactor Centre.

The project, which will be carried out in collaboration with the Division of Radiation Science and Acoustics of the National Physical Laboratory, will involve careful measurements of neutron spectrum shapes at U.L.R.C. and at N.P.L. The effect of changes in epithermal neutron spectra on the measurement of resonance integrals will be investigated.

Applicants should hold, or expect to obtain in 1979, a good honours degree in Physics, and should have been resident in the United Kingdom for at least three years.

Application forms and further particulars are available from Dr T. D. MacMahon, University of London Reactor Centre, Silwood Park, Sunninghill, Ascot, Berkshire SL5 7PY. 393(F)

GRANTS

THE ROYAL SOCIETY
SCIENTIFIC PUBLICATIONS
GRANT

Applications for grants from the first allotment of the Scientific Publications Grant for 1979 should be made not later than May 22, 1979 on forms obtainable from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG. The grant is for the assistance of scientific publications in the United Kingdom, particularly, but not exclusively, those of scientific societies and institutions.

Applications are receivable only from societies and institutions in the United Kingdom and individuals of British nationality. 380(N)

COURSES

IMPERIAL COLLEGE
M.Sc. IN ATMOSPHERIC
PHYSICS AND DYNAMICS

A study of physical and dynamical processes occurring in the atmosphere and oceans with specialised options in atmospheric physics and meteorology. The third term is devoted to the preparation of a dissertation.

Entrance requirements: First or Second Class Honours degree in physics or mathematics.

Grants: S.R.C. and N.E.R.C. advanced course studentships.

Further enquiries to: Dr J. S. A. Green, Atmospheric Physics Group, Imperial College, London SW7 2BZ. 390(D)

Nature Binders

Keep your copies of Nature
protected in durable black PVC
binders:

- * 20 plastic retention strips mean no loose parts, wire, or complex loading systems
- * title blocked in gold on spine
- * panel on spine for your own references

Each binder is designed to take two
volumes of Nature; three binders
will serve for a year.

Prices (including postage):

UK £3.00 each, three for £8.00

Rest of World US \$6.00, three for US \$16.00

Orders with correct remittance should be sent to:

Nature, Circulation Department,

Macmillan Journals Ltd,

Brunel Road, Basingstoke,

Hampshire RG21 2XS, England.

A new approach in tissue culture

PETRIPERM
 a novel culture dish with gas permeable membrane as cellular support.

Additional advantages of the PETRIPERM membrane are:

- UV permeable 200 nm
- Suitable for high power light and fluorescence microscopy
- The membrane can be cut for cell cloning, electron microscopy, staining and documentation
- Chemically resistant to acids, bases and organic solvents

PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.

In the intact animal, the pH and the partial pressure of both oxygen and CO₂ of the cell environment are under total biochemical and physiological control. This state is not even approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. PETRIPERM is the prerequisite for the precise control of pO₂, pCO₂ and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable 25 μm thick membrane.

Perfect photo-micrography at the touch of a button.

With the Wild MPS-System.

The new Photoautomat from Wild Heerbrugg represents a tremendous stride in the recording of microscopy specimens; an assurance of optimal exposure, superlative imaging and planned work. Everything has been automated: camera factor change between formats from 35 mm to 4 × 5"; super-sensitive exposure measurement for films from 5 to 43 DIN; exposure corresponding to film emulsion, with or without correction for reciprocity failure; film transport. Just concentrate on the specimen and on composing an expressive format.

Circle No. 04 on Reader Enquiry Card.

Press the button, and everything is taken care of. This doesn't mean that the Photoautomat jealously guards its secrets! The control unit displays not only the exposure time, but also the percentage of time elapsed, both of which can be influenced individually. That's how photomicrographs are made in series with the Wild MPS. Professional ones.

The various MPS systems for microscopes and stereomicroscopes are described in a colour leaflet. Ask for it.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; $\exp(a)$ is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258,1 (1975) and 264, v, 11 Nov. (1976)

19 April 1979

The voice of the people—which one?

ONE of the unmistakable trends of the 1970s has been for the question of risk—its measurement, perception and acceptance—to move progressively away from being a purely technological problem and towards the centre of the political stage. Scientists and technologists may have been able to come up with numerical values and probabilities and indeed as a result of their work immense strides have been made in raising safety standards. But a never-ending succession of accidents, major and minor, continues to remind us that the risks of a technological world, be they from unsafe drugs, faulty nuclear reactors, wrecked supertankers or whatever, come largely from human and institutional frailty and not from imperfect materials or inappropriate differential equations. Small wonder then that risk is now a political issue.

Many scientists and technologists are bitter about the way apparently technical issues have been taken over by social scientists, bureaucrats and politicians. It would be wrong totally to dismiss this bitterness as professional narrow-minded jealousy without giving some thought to whether an embittered profession will attract the ablest young people to it. Nevertheless, the problematical nature of the interaction of humans with technology, as controller as well as potential sufferer inevitably means that wider circles of opinion are now being sounded out, and that even wider circles may have to be consulted in the future. But what exactly does public participation in the handling of technological risk questions mean? This was one of the important issues raised at a recent seminar in Berlin organised by the European Economic Community and the European Committee on Research and Development (CERD).

If decisions are not simply to be handed down from remote technocratic elites, responsible only to themselves, it is all but inevitable that there will be dissension, some of it vigorous. And as Dorothy Nelkin of Cornell put it, "resolving conflicts is much like seeking 100% risk-free technology—hardly a feasible goal". What has to be done is that all sides must see that their case is at least taken into account by whoever makes the decision, and they must be satisfied that the choice of decision-maker and the form of inquiry does not prejudice the case. Apparently harmless criteria—yet it was striking how many unsatisfactory cases could be cited where the decision was a foregone conclusion or where objectors found themselves seriously hindered.

That said, however, a striking theme to emerge from the seminar was that objectors to technological developments on grounds of unreasonable risk should be smoked out on what they really stand for. This, it was suggested, could be done in two ways. First, they should be asked whether they were aware of the consequences of saying no to particular projects, and had thought them through as carefully as they had thought through their objections. Second, many objectors to technological projects do so not because they disapprove of one particular proposal at one particular place, but because such projects go against their total sense of values. In the words of Jerry Ravetz of Leeds "we must recognise that we can no longer follow the politics of 'economism', where quantitative differences can be negotiated between opposing sides; rather we must accept some features of the politics of 'ethnicity', where deep differences of values must be confronted and then used for the mutual education of both sides".

It is clear that there is absolutely no agreement about just how widely views on risk should be canvassed. When three out of four drivers, given a chance, will spurn the use of a seat-belt for no apparent reason whatever, it is obvious that thinking by the man-in-the-street about risk-taking is immensely complex, not to say irrational. So how do we represent—indeed who represents—this man-in-the-street, and is this element of irrationality to be despised or to be allowed for? The problem is that we may be in danger of replacing a technological elite by yet another elite which thinks it knows what the public wants or ought to want. The long-term answer, and this should be regarded as a long-term problem not just here for a few years, must surely lie in much more effective education at all levels in thinking about technology and risk. Few technologists are taught to think about social matters. Few social scientists are taught to think about technology in depth. It is here that progress must be made.

The European Economic Community could feel pleased with this seminar. It is a subject peculiarly appropriate to the community. Individual nations cannot at present muster the resources to take an omnidirectional view of the subject. Yet each is having to cope with a set of broadly similar problems in its own distinctive way. What more valuable than to let these varying patterns rub off on each other under EEC auspices. □

Anti-war movements—heading for a 60s revival?

David Dickson reports from California on how critics of US military policy are beginning to tap the grass-roots energy of the anti-nuclear movement

It might have become a formula for instant nostalgia. But when the film version of the 1960s anti-war musical *Hair* opened in California a few weeks ago, it was reviewed—and widely praised—at face value, with few claiming that its sentiments belonged to the previous decade. And taken with the success of two other anti-war films in last week's Oscar awards, the popularity of *Hair* suggests that these sentiments remain close to the surface.

In Washington, concern about the security of Middle East oil supplies is already generating the type of discussion about 'protecting natural interests' that preceded the military intervention in Vietnam. And a question now being debated on many campuses throughout the US is whether opposition to a growing military budget and to an increasingly hawkish administration is likely to coalesce into something comparable to the anti-war movements of the 1960s.

To judge from the situation in California, such a coalescence may not be too far away. At present, various groups are concentrating on a number of different objectives, some only distantly related to one another. But growing concern about US military policy in general—together with unease about nuclear energy in all its forms after the Harrisburg accident—are beginning to draw these groups together.

Some of the more recent events include:

- At the University of California's Berkeley campus, a senate policy committee has recommended that the university sever all links with its Lawrence Livermore and Los Alamos laboratories, claiming that the large proportion of the activities of the two laboratories devoted to weapons research make the involvement of the university—currently responsible for the management of each—"totally inappropriate".

- A number of Californian and anti-nuclear groups are expected to take part in demonstrations outside the university demanding that the laboratory's skills and resources be turned "totally towards peaceful research" as a way of putting the cap on the arms race.

- At Stanford University, a group of students is mounting a campaign to oppose legislation being discussed in Washington for revising the draft. One of the first speakers to address a

university meeting on the issue was David Harris, student president in 1966-67 who spent 20 months in prison for draft evasion.

- A number of requests has been received by the American Association for the Advancement of Science to place public discussion of the US military budget and its implications on the agenda of next year's annual meeting in San Francisco.

- A Berkeley group has published, through the Washington-based Institute for Policy Studies, a pamphlet on "resurgent militarism", claiming that "all struggles for social progress . . . must confront the new militarism", and that otherwise "the likelihood of nuclear war will surely increase".

Such concerns are by no means confined to the West Coast. At a national level, church and religious leaders have, in particular, put military spending at the top of their agenda of items of social concern, both on a national and an international basis.

Similarly anti-nuclear groups, once concerned primarily with the safety parameters of energy policies, are making the links to military policy. "If you've done your homework you know you cannot separate the two issues" says Marta Daniels of the Trident Conversion Campaign, the sponsors of a mass demonstration in Groton, Connecticut two weekends ago at which 229 persons were arrested for trying to block shipyard entrances to guests arriving for the launch of a new nuclear submarine.

But it seems to be on the West Coast, with its high concentration of both defence-related industries and veterans of the anti-Vietnam campaigns, where the linkages are being most tightly drawn.

One focus in particular has been the relationship between the University

Flashback to the 1960s: anti-war protest fills the street.

of California and the two weapons laboratories which it manages for the Department of Energy. This link has long been a source of contention among university faculty and students and moves to sever it in recent years have been given a boost by a broader anti-militarism campaign.

Supporters of the current arrangement argue that being run by the university means the laboratories can both maintain the high quality of their scientific research, and remain free of industry or Washington-dominated influences to express their views. "The university connection is the best way to serve the people" says Ed Hammel of the Los Alamos laboratory.

Critics point out that every nuclear weapon in the US armoury was conceived, developed and tested by the two laboratories. "The laboratories are not academic institutions, they epitomise 'science with a purpose'", says one long-time opponent, Professor Charles Schwarz of Berkeley's Department of Physics.

Ironically, those on both sides of the debate agree that, despite wide disparities in the technology, concern over the health hazards of nuclear power have linked the energy and weapons issues together in the public's mind.

Dr David S. Saxon, President of the University of California, sees public attitudes on both as a source of concern—but a situation for which scientists must share part of the blame. "The present unreasoning fear within this country and abroad of anything associated with the word nuclear is a reflection of an almost inexcusable failure within the scientific and pro-

Now nuclear power is seen as the guilty party.

fessional community involved in nuclear energy", he said recently.

"There has been a consistent unwillingness to react in responsible ways to the questions that members of the public ask. In too many instances the official attitude has been overbearing, arrogant and intolerant."

Dr Schwarz, on the other hand, feels that the type of concerns raised by the Harrisburg incident may—legitimately—spill over to what he considers a far greater health issue, namely the spread of nuclear weapons. "We have to show that the same institutions that run the nuclear power programme also run the nuclear weapons programme—and that we have been told the same lies. I am not against nuclear power in itself, but I am opposed to it because, as with nuclear weapons, I don't trust the people in control of it at the present time".

The university has itself been reconsidering its relationship to the two laboratories. A committee established in 1977 under the chairmanship of Dr William Gerberding, Chancellor of the University of Illinois, issued a report last year, suggesting that the university should continue to manage the laboratories, but through the operation of a powerful board appointed by the university, which would play a much closer role in overseeing the operation of the two laboratories than under present arrangements.

In an attempt to counteract charges that even under a board such as that proposed by the Gerberding committee, there would be little public discussion of the laboratories' activities, one university vice-president, Dr William Fretter, has proposed as an alternative arrangement the establishment of an advisory council to the university president, containing scientists, faculty members and students.

"I did not find the Gerberding proposals realistic, since the programmes of the laboratories—especially the weapons laboratories—are determined in Washington by the federal government, and it seemed unrealistic that these could be influenced substantially by a university committee", Dr Fretter said last week.

He argues that although the committee which he has proposed would only be an advisory one, it should

operate in public "since both the university community and the general community need more information on what goes on in the laboratories". Critics such as Dr Schwarz, however, maintain that since the committee would not deal with the laboratories' classified activities, and since it would have no executive responsibility—which would remain in the hands of President Saxon—it would lack any real teeth, and hence be little improvement on the current situation.

Debate within the university on the future relationship to the laboratories has been put temporarily on ice following the announcement in December that the Department of Energy was itself planning a review of the current arrangements. The department's report is due to be presented to Energy Secretary James Schlesinger next month, and is awaited with interest (particularly since, although being prepared by a subcommittee, the report is officially to be submitted by DOE's Energy Research Advisory Board—and this contains a number of individuals from the public interest community as specialists in alternative energy sources).

But if there is a pause in the official debate, grass-roots opposition is continuing to grow. The future of the weapons laboratories was among the issues raised at a mass rally held in San Francisco two weeks ago to protest at the opening of the Diablo Canyon nuclear power plant in the state, a meeting held under the shadow of the Harrisburg incident. And organisers of next month's demonstration at Livermore predict many thousands will turn up for a mass march, rally and 'peace conversion fair', with groups fasting at the laboratory gates, and others walking to the laboratory from all over California.

To judge from reactions elsewhere such activities are unlikely to be warmly welcomed by the university authorities. Last week a film crew was thrown out of Harvard University while trying to make a film about the 1960s protest movement. The film's director, Mr Jim Zinneman, admitted that a three-story mural showing some American soldiers trampling on Vietnamese "upset some faculty members and alumni". Nostalgia is not what is used to be. □

ISABELLE team denies setback

RUMOURS that the US ISABELLE project is having difficulties producing superconducting magnets for its 400 GeV proton-proton storage rings were denied last week by Dr Jim Sanford, the project head. In an interview with *Nature*, he said there were no problems with quadrupole magnet production, although they had run into difficulties with the dipole magnets.

Overall, progress was "90% satisfactory". "We are having problems in meeting the ultimate field of 5 teslas. We have reached 5 teslas in a model but not in the production prototypes. They are operating now at around 4½ teslas," he said.

The dipole magnets were first designed to operate at 4 teslas. The team made 13 model magnets and most of these exceeded this field. Recently the design was modified to operate at 5 teslas, and one model reached 5.1 teslas. However, when this was put into production, the magnets only achieved a field of 4-4½ teslas, Dr Sanford said. "We are not entirely sure what is causing this problem. Maybe it is the materials in the superconducting braid. We wanted to have a bigger margin than 5.1 teslas and so we added more niobium-titanium in the production, and in the process we may have lost some of the stability of the materials."

Production of the superconducting magnets is the major technological challenge of the ISABELLE project. The project has already had one setback—the US Department of Energy will only fund ISABELLE over seven years and not the five years the scientists had hoped for. However, Dr Sanford is confident the magnet problem will be solved by the summer so the contract for production can be issued by the end of the year. This will keep ISABELLE on schedule, and may even provide an argument for advancing to a 5-year target, said Dr Sanford.

In Europe, ISABELLE's competition in the race to produce the heavy intermediate vector boson, the CERN proton-antiproton experiment, is expected to produce hard evidence by 1982, said a CERN spokesman. □

UK and Sweden attack lead poisoning studies

A NEW US report on lead pollution published in *The New England Journal of Medicine* by a team of researchers from Harvard Medical School and the Children's Hospital in Boston has not been openly welcomed in Britain.

The study indicates that currently accepted lead levels may be set far too high to be safe for children in urban

areas. The team, headed by Dr Herbert Needleman, examined lead levels in children's milk teeth, which is considered to be a better indicator of long term exposure than blood lead levels.

Starting with a sample of 3,329 children, two samples matched for social and environmental variables including social class, mother's age and

parental IQ were constructed. The 58 high lead children (20ppm in dentine) and the 100 low lead children (less than 10ppm) were given standard psychological and mental tests. (The mean blood lead levels in the two groups were 355 µg/l and 233 µg/l, both of which are well within the normal range for children in UK urban areas.)

The results showed that the high lead children performed less well on all the tests including reaction time, word processing and standard IQ tests.

Professor Pat Lawther of St Bartholomew's Medical School in London and chairman of a Department of Health and Social Security working party on lead pollution in the UK calls the Needleman study "the result of very careful work" but says that the statistics "have to be gone into in great detail" before he could evaluate it. "There are 39 variables subject to regression analysis, and besides, behavioural studies are very difficult" said Professor Lawther.

According to Anthony Tucker, science correspondent of *The Guardian* newspaper, the DHSS working party has been primarily concerned with criticising earlier studies that showed lead induced behavioural changes in children in the UK. "But since no studies of this standard or scale have been carried out in Britain or elsewhere it is difficult to see how its findings can be refuted," writes Tucker.

Meanwhile one of Britain's specialists

on lead whose work is supported by Needleman's study, Professor Derek Bryce-Smith of the University of Reading, was subjected to some extremely unprofessional behaviour when he visited Stockholm recently to take part in a panel debate on lead and children. His visit followed a minor furor caused by the publication (in the journal *Ambio*) of an article which he co-authored, alleging that body lead levels considered normal in children actually appear to be pathogenic.

The article had prompted denials from two Swedish researchers, one of whom—Professor Åke Swensson—agreed to take part in the debate. In deference to Bryce-Smith, the Royal Academy of Sciences, which arranged the debate, announced that it should be held in English. This was duly printed on the programme and all the Swedes complied—except one. Docent Carl-Johan Göthe, ignoring the chairman's admonition and in spite of the fact that there was no official interpretation provided, announced that he would speak Swedish. He then proceeded to attack Professor Bryce-Smith, coming to the

very edge of personal insult. A little later he answered a question in English.

But Bryce-Smith himself was more disturbed by the behaviour of Professor Magnus Piscator, the other critic of the *Ambio* article. Piscator published his critique in a Swedish-language medical journal, accusing Bryce-Smith—among other things—of distorting information in some of his reference material. He made no attempt to contact Bryce-Smith to make his charges in English, and even refused to participate in the panel debate, saying it was stacked with people sharing Bryce-Smith's views—which was not the case.

"The allegation of distortion is untrue and libellous as far as we are concerned", says Bryce-Smith. "Piscator's article was extremely discourteous and unprofessional. His behaviour is very irresponsible and not in the best traditions of science."

Professor Bryce-Smith was not impressed, either, with the level of the debate. "These people do not seem to be aware of recent literature on the subject", he said, citing the Needleman paper. □

Soviet science boss refused Academy membership

SERGEI P. Trapeznikov, the Soviet top Party boss for science, has been refused full membership of the Soviet Academy of Sciences. So far as is known, this is the first time that the academy has ever refused an application from a member of the Central Committee of the Communist Party of the Soviet Union.

Trapeznikov is chairman of the Science Commission of the Supreme Soviet, and as such, formally has both the State Committee for Science and Technology and the Academy of Sciences under his jurisdiction. His appointment, however, was made on political grounds, not scientific. He has the reputation of a hardliner, and during the 1960s vigorously opposed the economic reforms proposed by Professor E. G. Liberman, which were aimed at loosening the Party's hold over the economy.

Since his appointment as Chairman of the Science Commission in 1968, Trapeznikov has tried several times to get elected to the academy. In 1976, he finally achieved the rank of "Corresponding Member" (i.e. Associate Member). Election as Corresponding Member, however, does not require a vote from the full General Assembly of the Academy, but only confirmation by the general assembly of a decision already made by the relevant section.

Applications for full membership, however, must be discussed by the general assembly, and are then decided

by secret ballot—the academy is the last remaining body in the Soviet Union to exercise this method of voting. It is due to this right of secret ballot that Academician Andrei D. Sakharov remains a member of the academy, in spite of several attempts to have him ejected.

Sakharov, indeed, took part in the debate on Trapeznikov's candidacy, stating that the latter's works on the collectivisation of agriculture were not of sufficient scientific value to qualify him for admission. Trapeznikov was rejected by a majority of 212 to 137.

Regarding these figures, it is interesting that Mark Popovskii, a journalist who emigrated from the Soviet Union in 1977 claimed in his book *Controlled Science*, that secret ballot notwithstanding, there are certain members of the academy who would never dare vote against the election of the chairman of the Science Commission. Discussing just such an election as an example of the degree of "humility" the academy shows towards the Party, Popovskii states that the Chairman of the Science Commission (i.e. Trapeznikov) has within his competence the appointment of the directors of scientific institutes, "one of the most longed-for jobs in the country". Secret ballot notwithstanding, Popovskii suggests that in such an election, although the "rank and file" academicians can "play their game of democracy", those who hold the post of director of an

institute simply would not dare.

Popovskii also relates a number of other cases when persons of political status but insufficient scientific quality have been turned down by the academy. These include the present Minister of Education, V. P. Elyutin, and the Minister of Health B. V. Petrovskii (The latter has in fact good medical qualifications, but medical personnel, however distinguished are not admitted to the Academy of Sciences—they must apply to the less prestigious Academy of Medical Sciences).

Some years back, however, the Academy of Sciences seems to have been more complaisant—during his term as Minister of Geology, Aleksandr V. Fedorenko managed to become a Corresponding Member (1953) and then a full Member (1966).

Why though should Trapeznikov and other politicians whose work verges on science be so keen for election to the academy? Is it simply a desire for increased status? Possibly. However, membership of the academy brings more than status; it includes a generous salary, and a number of valuable fringe benefits in housing and the like. Moreover, these are held, effectively, for life. Expulsion from the academy is virtually impossible, although it is reported that during the last few months the academy's statutes have been amended to ensure that anyone deprived of his Soviet citizenship would be automatically expelled.

Vera Rich

Czechoslovakia strengthens science and technology

LAST year, Czechoslovakia embarked on what was described as a "complex experiment in effectiveness and quality control"—which to Western observers seemed virtually a reform of the economy—save that "economic reform", to the Czechs, is an expression tainted by memories of the Dubcek regime. Last month, the meeting of the Czechoslovak Federal Assembly carried the tendency further, by virtually rejecting the figures for the next Five Year Plan—an event unprecedented in the history of the Czechoslovak Socialist Republic.

One change associated with the "complex experiment" was the re-organisation of the pay structure for scientific and tutorial staff at universities and other higher educational institutions. Addressing the Federal Assembly last month, Prime Minister Lubomir Strougal observed: "The salary conditions of scientific and tutorial staff of the higher educational institutes [polytechnics and universities] were regulated with effect from 1 October, 1978. We believe this, however, to be only one partial step designed to raise the interest of specialists from scientific and research institutes [which do no teaching] and from practical places of work in taking up jobs in higher educational institutes."

Although details of the new "con-

ditions" are not forthcoming, the trend accords with the general tenor of Strougal's speech and the other discussions in the General Assembly.

Czechoslovakia is the most reluctant member of the Comecon bloc when it comes to the purchase of foreign technology or know-how; the economic proposals outlined last month envisaged a cut-back in imports of all kinds and a greater dependence on home resources.

Officially, this change was linked to the word: energy situation. Since September, 1976, when the Soviet Union suddenly increased oil prices to Comecon, Czechoslovakia has had a growing energy problem, which has been only partially met by the staggering of working hours. Strougal's speech contained six major proposals in the energy sector: expansion of capital expenditure on home fuel and energy production, a crash programme for the development of the North Bohemian lignite reserves, intensified research into the "complex of problems" ranging from investment to social welfare) associated with plan fulfilment in the deep mines of the Ostrava-Karvina area, an extension of nuclear generating capacity to 3,500 MW by 1978 and 8,000-10,000 MW by 1990, further participation in transit programmes, allowing "various forms

of energy" (eg natural gas) from the Soviet Union to cross Czechoslovak territory and the implementation of fuel-saving programmes, aimed at saving some 20m tonnes of fuel per year.

Regarding this energy programme, Strougal noted that the total savings envisaged would not be possible immediately, but that substantial progress "must be registered in the remaining years of the current Five Year Plan, and especially in the next Five Year Plan". In his main speech the Prime Minister did not, of course, make any reference to the accidents which the Charter 77 movement allege took place at the Jaslovské Bohunice nuclear power station in January 1976 and February 1977.

It was left to a relatively minor member of the Assembly, Deputy Dana Kancirova, to raise this inauspicious subject. Even she approached it in a roundabout manner, asking for an explanation concerning the current Austrian press campaign about the safety of nuclear power stations. Mr Strougal answered, somewhat airily, that "our present and planned nuclear power stations are of the Voronezh type, different from the one at Zwentendorf". The alleged fatal accidents at Jaslovské Bohunice, he added, were simply "a fabrication of bourgeois propaganda". **Vera Rich**

Islamic scientists prepare for UNCSTD

Ziauddin Sardar discusses the Muslim countries' views on development and the role of Islamic science

THE Islamic Secretariat is to submit a position paper, representing the views of its 42 member countries to the United Nations Conference on Science and Technology for Development in Vienna next August. The paper is the final outcome of a conference held in Jeddah on 17-21 March and has at least two novel features: it is the first effort by the Islamic bloc to represent an Islamic viewpoint on science and technology at the level of the United Nations and it forces the Muslim countries to recognise that there can be no effective development without the evolution of indigenous science and technology.

Implicit in the first point is the assumption that there is an Islamic alternative to the conventional practice of science and technology. That the Jeddah conference could not go beyond vague statements of this alternative is not surprising: the Muslim civilisation has been dormant for over three hundred years and current ideas on Islamic

science and Muslim technology emerged only at the turn of the decade. Clearly there is a great deal of work and much analysis to be done before anything concrete emerges. The Islamic Secretariat paper provides recognition to these ideas and should give them an international hearing.

The second feature is important because, when the paper is endorsed by the Tenth Islamic Conference of Foreign Ministers in May, the Muslim countries will become actively committed to the establishment of ministries and/or other high-powered bodies for science and technology. This may not appear to be much of an achievement from the perspective of the industrialised countries, but only half a dozen of the 45-odd Muslim countries currently have ministries and other national bodies devoted entirely to science and technology.

Billed as "The First Muslim Science Conference", the Jeddah meeting was convened by the Ninth Islamic Confer-

بِسْمِ اللَّهِ الرَّحْمَنِ الرَّحِيمِ

الإسلامية العالمية للعلماء والتقنيين

Emblem of the Islamic secretariat

ence of Foreign Ministers, held in April 1978. The science conference itself was a shambles. Of the thirty-odd delegates who attended only seven could be classified as scientists; the rest were all career diplomats. Although it was never openly admitted, the dominant presence of the civil servants was clearly embarrassing to the scientists who were eager to produce a powerful position paper.

What is surprising is that the scientists managed to carry the conference and produce a coherent and

reasonably well argued paper. They see UNCSTD as the first step towards the establishment of a "new world order in science and technology". Dr A Abou El-Azm, who is tipped to be the first director of IFSTD, argued for a strong action-orientated paper that does not undermine the position of the Group of 77, and Dr Ali Mohammed Kamel, a consultant to the Arab League Educational, Cultural and Scientific Organisation (ALESCO) repeatedly asked for the paper to be connected with the call for a New International Economic Order.

Dr Waqar Husaini of the Civil Engineering Department, King Abdul Aziz University, was more concerned with emphasising the issues of ethics and morality of science. "Islamic development", he argued, "is concerned with individual and self-purification and with growth that does not transcend the ethical boundaries of Islam. Science and technology do not have an independent existence under Islam. To the contrary, they are subject to the value principles of Islam"—a point that was also echoed by other delegates.

Dr Yalgin Tuncer of Middle East Technical University was not very optimistic about the outcome of UNCSTD and argued that the Islamic position paper should be addressed not so much to UNCSTD but more to Muslim countries. "We should have a crystallised model of Islamic science and technology and its role in development; and we should offer this model to Muslim countries for study and application", he said. It was finally agreed that the paper will address the UNCSTD meeting, the Muslim countries and IFSTD.

The paper airs many concerns common to the developing countries; the lack of awareness in the Muslim world of the key role of science and technology in development; the quality and quantity of available manpower; the brain drain; the exploitative practices of western governments and multinational corporations in the field of technology transfer; lack of information on the choice of available technology; and the adverse repercussion of the politics of aid.

Unfortunately, examination of these issues is devoid of self-analysis. Placing the shortcomings squarely at the door of the West has become a common practice with the developing countries. The Islamic Secretariat's paper could have provided a lead by closely examining the attitudes and outlooks that prevent science and technology from taking indigenous roots in the Muslim world.

Also absent from the paper is an awareness of the ideological stance of science. The Islamic Secretariat's paper asserts that "there are no ideological obstacles to a vigorous introduction of science and technology in Muslim coun-

tries". This is not altogether true. Traditional Muslim intellectuals do not see science as an entirely value-free, apolitical activity; and their experiences have confirmed their views. The Islamic Secretariat's paper largely overlooks this viewpoint and asserts that problems only exist in the realm of transfer and adoption of technology.

However, a slight awareness that the situation may be more complex appears in the statement that "it is not always possible to separate science and technology from the philosophical background and social forms attached to them in their country of origin". Hence, it is argued, it is necessary to develop an Islamic philosophy of science. The paper states: "Science is a common human heritage and almost all nations have contributed to it at one time or another. Muslims, in particular,

have made some of the most decisive contributions. . . . Hence it is an absolute fallacy to see science and technology as the sole product of Western culture". But there is an inductive leap that leads the paper to conclude that it is therefore possible to fit conventional practices of science and technology into Islamic social and ideological systems. The first step towards this goal is said to be the popularisation of education, training and the professional practice of science and technology. Here there is an acute shortage of good technical translators and qualified scientists who can teach in indigenous languages. Those who can teach do so only in a foreign language, for they themselves were either trained abroad, or by foreigners locally. Scientists and technologists trained abroad, particularly, present a tremendous resistance against popularisation.

The paper rightly blames the frustration of local scientists on the *en masse* transfer and purchase of western technology. This is why the Muslim countries "have not developed locally effective institutional mechanisms and expertise to ensure performance of various functions for assessment and

selection of appropriate technologies and for successful implementation and adoption of these technologies in the productive sectors". But in turn, this technological weakness is the main reason for the failure of technology transfer and for the technological dependence of the Muslim world. The prescription for shaking off this dependence asks Muslim governments to individually and collectively: formulate their policies for choice, transfer, and development of technology; build up an infrastructure for creating and using technology; and develop competent manpower.

Although it is not specifically stated, the paper assumes that at present Muslim governments do not have science and technology policies worthy of the name. A comprehensive science and technology policy is seen as a "fundamental pre-requisite for self-reliance and self-development". Further, this policy "should be integrated with the Islamic socio-economic objectives and policy and be consistent with its development priorities . . ."

The best way to turn the brain drain into the brain gain, says the paper, is to introduce and strengthen the internal "pull-factors". Such "pull-factors" could include "an Islamic socio-political environment, facilities for intellectual growth and professional satisfaction, logistic support at home and place of work that enables the scientists and technologists to be efficient and productive, proper salaries and privileges, merit-based promotion and recognition through a system of rewards, in-service training, continuing professional advancement, visits to advanced countries etc."

This oft-preached solution has one unusual recommendation: the developed countries should be persuaded to adopt legal measures against immigration and employment of skilled Muslims from developing countries without their governments' consent.

Science and technology resources in the Muslim world are scarce. The paper's plea to the Muslim countries to share and pool their resources, therefore, makes a great deal of sense. Many Muslim countries face similar development problems. Obstacles to development in these areas could be eliminated by effective cooperation and joint action programmes. IFSTD, the paper states, will be a catalyst in this process of cooperation and coordination.

Despite its many shortcomings the importance of the Islamic Secretariat's paper for the Muslim world cannot be underestimated. Even if only half of its recommendations are actually followed up by the Muslim countries, it could change the status of science and technology in the Muslim world. And that would be no small achievement. □

Gargamelle may be scrapped: CERN's heavy liquid bubble chamber, Gargamelle, which was the first to detect the weak neutral current and has been in operation since 1970, may be at the end of its life. Last year a leak was detected in the chamber that proved to be easily identifiable and repairable. But the chamber was sent to the factory for further inspection, to check the welded joints, and micro-cracks were discovered in the welds. The cracks are currently under investigation and a decision will be taken on the chamber's future at a meeting on 19 April. Engineers have given negative advice saying that repairs will be very costly, of the same order of magnitude as the cost of building a new chamber. Another consideration is whether the chamber would be in violation of Swiss safety standards. Gargamelle is used as a neutrino detector and its loss would leave only the BEBC heavy liquid chamber for neutrino physics, a considerable cut in detecting power. The loss would come at a particularly inopportune moment, as CERN is to reach 450 GeV this summer, doubling the neutrino flux to the two chambers.

Soviets respond to Harrisburg: Soviet nuclear planners have taken the opportunity of the Harrisburg disaster to defend their own commitment to fast breeders. Within the last few days, Moscow radio has put out two major interviews which, while not mentioning Harrisburg explicitly, are a clear comment on the situation.

In the first, an English-language transmission to North America, Dr Andronik Petrosyants, the Chairman of the USSR State Committee for the Utilization of Atomic Energy, said that although to date the Soviet energy programme had been based mainly on 'conventional reactors' (with experimental fast-breeders at Obninsk, Dmitrovgrad and Shevchenko), long-term plans envisage a change-over to fast-breeders, a field in which Soviet scientists "cooperate with their counterparts in the US". Petrosyants added "Only such reactors will enable the industry to develop sufficiently fast and on a large enough scale". Later he explained that the Soviet applications of fast-breeders, which "are limited by scientifically motivated standards, present no radiation hazards".

In a programme for the home audience, Anatolii Aleksandrov, President of the Academy of Sciences of the USSR described Soviet plans for constructing nuclear power stations in urban residential areas, which should, he claimed, halve the cost of district heating. Plans are also under way, he said, for using power stations as a source of heat to cut the cost of "relatively expensive technological processes such as those involving powder metallurgy".

Orlov told to stop issuing research notes: Yuri Orlov, the Soviet physicist at present serving a 7-year labour-camp sentence for his activities in defence of human rights has been forbidden to include in his fortnightly letters home any mathematical formulae or other material which the camp guards cannot understand. Ironically, his wife received this information about 10 days before *Nature* published extracts from his letters, in which he described his attempts to keep up some form of theoretical research.

Banning of the intellectual activity of dissidents is nothing new in Russia. In 1847, the Ukrainian poet, Shevchenko, was sentenced to 25 years in an army penal battalion, "with the express prohibition of writing or painting", added to his sentence in the Tsar's own handwriting. It is not known at what level the ban on Orlov's intellectual activity originated. Mrs Orlova thinks that it probably originated with the camp guards themselves. However, a friend of the Orlovs told *Nature*, no guard would take any initiative

he did not think would be approved higher up. This friend also pointed out that in Orlov's last "scientific" letter from the camp—a paper on wave probability—he indicated by a periphrasis that he hoped it would be published abroad.

Portugal doubtful about Soviet Atlantis find: Recent claims by Soviet oceanographers that they have discovered traces of a city on the floor of the Atlantic have been treated somewhat sceptically by their Portuguese opposite numbers. After discussing the "finds" with the Soviet team, Dr Marcello Vasconcelos, head of the Portuguese National Institute for Fishing Research, admitted only that "It is undeniable that they have found something". He and his colleagues at the Institute could not give a professional opinion on the reported find, he explained.

Dr Vasconcelos said that the Soviet scientists appeared to be "highly optimistic" about their photographs which, they claim, show ruins of a city some "320-480 km" off the coast of Portugal, in the direction of its "mid-Atlantic island possession, Madeira". Dr Aleksei Aksenov, the head of the Soviet team, claims to have taken eight photographs, showing "vestiges of walls and stairways". Further details, including the depth of the alleged finds, will, according to Dr Aksenov, be announced after further study of the photographs in Moscow. Soviet opinion, he explained, was that the discovered remains could well be the "lost continent of Atlantis".

Soviet oceanographers would appear to be having great success recently in explaining Atlantic "mythology". Last year, another oceanographic expedition reported huge "vortices" in the Bermuda triangle region.

UK proposes major microprocessor research and training programme: The Science Research Council in the UK has adopted the recommendations of a Council panel which call for a major programme of additional academic research to "help the UK get maximum benefit" from microprocessors and programmable electronic technology. The panel makes specific recommendations in the areas of education and training, new computer applications and new computer technology. In education, the panel proposes a centrally coordinated programme of six five-year projects to expand existing commitments such as the National Development Programme in Computer Assisted Instruction. The panel envisages 1,000-2,000 "work stations" that will use the new technology for education and it calls for the appointment of a Programme Director "at an early stage". In addition the panel proposes 50 research studentships per year in computers and microelectronics, conversion courses for "arts graduates (or unemployed teachers)" and additional fundings to attract PhD and MSc students.

In new computer applications the panel emphasises the importance of industrial robotics both for UK application and for export. The panel asks the SRC to appoint a Programme Director to carry out an "in depth study" of the UK situation over the next 12 to 18 months and it recommends the creation of an SRC professorship in this field "in a major location." The Rutherford Laboratory is proposed as a centre for research into increased uses of microprocessors in measurement and instrumentation as well as for research into the next generation of silicon chip design and test automation.

The SRC has appointed an Implementation Group chaired by Professor J. Brown of Imperial College to draw up detailed costs and to liaise with other concerned governmental bodies.

Steady progress on the 'long march' to modernisation

Jen Tsi Yang, professor of chemistry at the University of California, San Francisco, on the revitalisation of science in China

THE People's Republic of China is embarking on a grand programme of Four Modernisations: in agriculture, industry, national defence, and science and technology. An aphorism by the late Premier Chou-En-lai, "Dare to think, dare to say, dare to do! Work hard, work with energy, work with ingenuity!" can serve as a battle cry for what is being called a New Long March (*Xin Chang Zheng*) or even a New Liberation (*Xin Jie Fang*). After a turbulent decade from 1966 to 1976, an openness (within limits, of course) and a new mood of enthusiasm are evident. During a recent visit to China my hosts talked to me uninhibitedly about many subjects, both scientific and more wide-ranging. Amongst them were some horrific stories—for which the now toppled villains were blamed in nearly all my conversations—which are better left for future historians to sift through. My observations on science in China are not intended to be comprehensive, but will indicate the progress being achieved.

Education is the key to the modernisation programme. China is racing to train a vast phalanx of scientists and technologists. The country lost a generation of educated manpower during the Cultural Revolution, starting in 1966. Schools were closed for several years, and the students of universities, colleges and secondary schools went on a rampage while the teachers were subjected to repeated confrontations and inquisitions. Yet these students received promotion every year and "graduated" automatically. Millions of them were later sent into the countryside and still live there. The sudden change in political climate in October 1976 has produced a renaissance fervour for learning. The few cities I visited, including Shanghai, Nanking and Peking, reflect this new atmosphere now sweeping the country. Books on science, technology and primers of foreign languages, especially English and Japanese, are in great demand, and a new English-Chinese dictionary has already sold out. The libraries are once again crowded.

Nationwide college entrance examinations were held in December 1977 and July 1978. The applicants were appraised morally and physically as well as intellectually. No longer, I was assured, are the children and grandchildren of workers, peasants and soldiers automatically favoured for admission. To avoid corruption in the form of backdoor dealings, each appli-

cant was allowed to check his or her score, calculated to the first decimal, against the announced pass mark, which was adjusted geographically to give a balanced distribution of successful applicants. Having cleared this first hurdle, each applicant had a physical checkup and an evaluation of his or her moral character. Both former 'graduates' from the bad years and those fresh from high school competed for this educational opportunity. Many did well in the exams by dint of cramming, either alone, or with the aid of tutors.

The present education system comprises periods of five, three and two years at elementary, junior high and high schools respectively, and four years in college or university (five years in medical college). Currently, 88 institutions are designated as *chong dian* (literally, main-point) or key universities. Initially, about 200,000 freshmen were to be accepted in 1978, but this number has been enlarged, perhaps even doubled, and many universities have set up branches to accommodate the increased enrolment. In addition, the graduate training programme has been restored as a three to four year course, although details are still to be worked out. This has led to the danger that the teaching staff could be overburdened by the combination of increased teaching loads with new activity in research. More serious is the risk that tensions may build up between the educational "haves" and "have-nots", especially those millions sent to the countryside, who do not get as far as the entrance exams.

In the 1950s China adopted the USSR educational model, which is now being modified. At present a comprehensive university is essentially a large college covering both letters and science, while schools of engineering, agriculture and medicine are separate colleges or universities (depending on size). Under the old system, incoming freshmen were required to choose a specialised subject (*zhuan ye*), and the students were denied a spectrum of courses beyond their specialities. China's new plan is to teach basic courses for 2½ to 3 years and the students will have freedom to choose one *zhuan ye* in their final year.

Three major speeches delivered at the National Science Conference in March 1978 have now been published in the "Documents of the National Science Conference" by the People's

Publishing House (*Renmin Chubanshe*). They contain the blueprint for the Four Modernisations. The State Science and Technology Commission, headed by Vice Premier Fang Yi, now administers all the research programmes in the Academia Sinica, universities and colleges under the Ministry of Education, and various industrial ministries.

The Academia Sinica (or the Chinese Academy of Sciences) is traditionally the cornerstone of basic research in the natural sciences. The academy has many branches all over the country and it also administers four universities. (In addition, there are municipal and provincial academies of sciences.) At present the academy has more than 100 research institutes in some 20 cities, Peking having 40 and Shanghai 15. There are about 30,000 researchers and 20,000 administrative and non-technical staff. Research institutes also train their own graduate students. It seems to me that these institutes could benefit from bringing in researchers trained elsewhere, and from having their scientists participate in university and college graduate training. Such cooperation between the institutes and schools is crucial to the crash programme of modernisation. While a certain degree of competition between institutions is an incentive for excellence, Chinese researchers face a real problem in "mountain-topism" (the establishment of rival empires); because of the shortage of scientists, both the universities and research institutes want to keep their best trained graduates. I believe that this is a waste of manpower, and furthermore, the in-breeding does not expose the graduates to a suitably broad spectrum of knowledge. Ideally, the universities should train the graduates and the institutes train the post-doctoral staff (although no degrees are offered in China).

Gone are the anti-intellectual Workers' Propaganda Teams which once controlled the institutions, and established scholars have again been called upon to administer institutions, albeit under party leadership. While the loss of a generation of educated young is most tragic, one should also spare a thought for the frustrated middle-aged researchers who have wasted the most creative decade of their lives. At present China's institutions have many senior faculty and researchers, but not enough well-trained junior investigators under the age of 35. This gap will close when a new crop of graduates joins the rank of their elders, for junior faculty and staff are again being professionally evaluated for pro-

Education is the key to modernisation

motion, after a lapse of more than ten years. They will succeed the ageing generation of Western-trained scholars and will have to shoulder the main burden in the immediate future. I can attest to the fact that the new political climate has brought about a euphoria amongst Chinese educators and researchers, both young and old.

Under the incentive to catch up rapidly, "glamorous" research projects are naturally the most attractive, and I think China must be very careful that fundamental research does not suffer as a result. Genetic engineering is a case in point, for despite considerable enthusiasm for such topical research, the universities and research institutes are really so poorly equipped at present that I think it unwise to seek glory and neglect the basic facilities.

Visiting scientists are welcomed as foreign guests (*waibin*) and given VIP treatment. Such visits expose Chinese researchers to the current state of knowledge and level of thinking in their fields. China-born scientists now living abroad, often called the people's relatives, are especially sought after, for their ability to teach with no language barrier and to advise with the benefit of a common cultural background. Many of us, with close kinfolk in China, have made repeated visits in recent years, for while we are loyal to our adopted countries, we are proud of our heritage and most of us are willing to contribute regardless of ideological differences. Normalisation of Sino-American relations is bound to multiply such scientific exchanges. Not many such visitors can extend their stay for too long without affecting their own research but sabbatical leaves and collaborative research projects may provide longer-term scientific contact. China is now sending abroad hundreds of graduate students for training, experienced researchers to expand their knowledge and numerous scholars to attend international meetings. The impact of these returned scientists and technologists is bound to be immense and not confined to science.

Chinese scientific journals are being revitalised. The bimonthly *Scientia Sinica*, a comprehensive journal for the natural sciences, with some articles on agriculture, medicine and technology, resumed publication in 1973 and is scheduled to be published monthly in 1979. Most, but not all, papers in the Chinese and foreign (predominantly English) editions are identical. Currently, the editor-in-chief is a vice president of the Academia Sinica; he is assisted by an associate editor and an editorial committee of 106 members as well as an editorial staff. Other Chinese journals such as *Acta Biochimica et Biophysica Sinica* have both Chinese and English abstracts. In a departure from the formats of early years, political slogans and quotations are generally absent from scientific texts, and collective (anonymous) authorship by a laboratory may also be declining. *Kexue Tongbao* (*Science Bulletin*), which was also re-launched in 1973, will concentrate on short communications in sciences in 1979. This monthly publication will soon become semi-monthly, and a foreign edition is being planned. Recently, *Nature* has accepted the first paper from the People's Republic of China (Ho, Y.S. & Tsou, C. L. *Nature* **227**, 245-246 (1979)). This could presage a trend for Chinese scientists to summarise their best work in foreign journals. English has now become the language of science, and Chinese students once again study English from the third grade through the college freshman year.

The term 'science management' is frequently heard in China these days. The best use of available manpower and resources, and the financing of the astronomical cost involved, are central to the success of modernisation. In October 1978 Vice Premier Fang Yi toured Western Europe, and Yu Wen, secretary general of the Academia Sinica, headed a delegation to study US science policy-making, peer review, and research and development management. Similar delegations of science managers are also being sent abroad.

But mobilisation of bureaucrats in any country is not easy. In Peking a street sign for pedestrians reads: "one, slow; two, look; three, cross the road," and this rubric has been applied to those cadres who, uncertain in which direction to proceed, hesitate and prefer to cleave to established routines. The New Liberation should be a liberation of thought, for only then can "a hundred flowers blossom!" The unparalleled vicissitudes of the past decade have left many people with a sense of *xin you yu f* (the heart still palpitates).

It is often said that Chinese scientists work at a slow pace. This I believe is no reflection on their energy and competence; they have simply been left with so appalling a legacy of problems that they need time to re-adjust. Shortage of technical assistance and lack of modern facilities must be remedied. One mundane fact is that Chinese intellectuals must spend much time on domestic tasks. Young people could easily spend one third of their working hours on non-scientific chores. It might take a woman one hour or so for the daily grocery-shopping (the majority do not have refrigerators). They wash clothes by hand. Couples with babies too young to go to the nurseries must cope with the baby-sitting problem. In addition, both husband and wife work; this further reduces their working hours on science. I believe that it would be detrimental to the national interest to treat the intellectuals as a superior class, which may become alienated from the masses, but workers would become more efficient if they were relieved of some of the more acute problems of daily life.

China can accomplish almost anything, but not all at once. There is always a danger of trying to do too much too fast when political and economic conditions may not yet be ripe to absorb such drastic changes. After nearly 30 years the people are demanding a modern nation with a higher standard of living, and over 80% of China's population live in rural areas (compared to under 4% in the US), where the struggle for the necessities of life is more arduous than in the cities. The scientists and high officials all want to speed up the modernisation programme, but the bureaucrats may be too slow to make the necessary response. China-watchers estimate that the programme will require several hundred billion dollars over the next eight years. With Chinese oil still in the ground, and little to export for raw materials, China's economic problems can be tremendous. But the Chinese people are pragmatic and determined, and given unity, stability and unanimity of grass-roots support, China should succeed in her long march towards modernisation. □

Association of Geoscientists for International Development

SIR,—Your timely editorial "After geodynamics, what?" (15 February, page 503) was read with interest.

From the tone of the editorial, however, it appears that you have not yet become familiar with the Association of Geoscientists for International Development (AGID). Originally conceived at a symposium on the role of the geosciences in international development at the 1972 International Geological Congress in Montreal, AGID has grown to a membership of 1,100 geoscientists in 95 countries in its roughly five years of active existence. In this time it has held several symposia and workshops aimed at fostering technology on problems in developing countries, and, more particularly, at increasing the capabilities of developing country geoscience communities. Such topics as geoscience education in developing countries (Australia, 1976), geochemical exploration in the tropics (Zambia, 1977), and mineral exploration in the tropical rain forest (Venezuela, 1977) have been treated in this manner.

Among AGID's several publications are a quarterly newsletter, a directory of university geoscience departments in developing countries, a bibliography of groundwater reports pertaining to LDC's, and a critique of geoscience-related development aid.

Though it has kept a low profile in many 'developed' nations, AGID is well known in its area of emphasis from the abovementioned workshops and publications, for its surplus literature exchange (enabling organisations with insufficient foreign exchange for purchasing geological publications to obtain such materials that were donated as surplus by others), its appropriate technology referral and other services, and by the activities of its members.

AGID has sometimes been considered mainly as a means of technology transfer. But technology transfer is not AGID's only purpose, nor, certainly, is this an activity unique to AGID. Perhaps its unique challenge is to overcome the lack of emphasis on, and knowledge of, the peculiar geological environments found in developing countries which by themselves currently have limited resources for attacking these problems individually. Basic problems such as the effects of tropical weathering on geochemical dispersion, and of seasonally fluctuating water tables and surface wetness on geophysical exploration in tropical environments have received almost no attention; and engineers are often still caught designing structures around the assumption that a granite will hold a steep slope indefinitely (when the feldspars quickly weather to clay in the humid tropical environment, producing rapid slope failure). For the above reasons the need for an international institute, somewhat similar to the International Centre for Theoretical

Physics at Trieste but located in a tropical environment, is even more critical to the geosciences than to theoretical physics. Although AGID's workshops have attacked some of these problems, the need for a continuous institution directed at improving geoscience capabilities worldwide has been a goal of the Association since its inception. It has just completed an overall plan for such an institute, based on the experiences gained from its workshops and of its members.

The Association has received generous support from the Canadian International Development Agency, the (Canadian) International Development Research Centre, and the governments of Venezuela and Nigeria. Modest contributions have come from other sources, such as the Commonwealth Foundation. Nevertheless, AGID's accomplishments have been achieved on a shoestring budget.

From this you can see that the "secretariat" that you are seeking already exists. It has an advantage over attempts to organise such an effort from other existing institutions in that it is already in existence solely to develop the geoscience community where it most needs development. With its broad international base and its headquarters in Caracas it is less likely to become misdirected in its efforts than might a newly created secretariat in Europe or North America.

AGID heartily welcomes partners in its activities. People interested in its goals, as well as financial support are solicited. It is also interested in assisting in ongoing or planned projects, should such assistance be desired, and consistent with its goals. Correspondence can be addressed to Dr A. Bellizzia, Secretary, Association of Geoscientists for International Development, Ministerio de Minas and Hidrocarburos, Torre Norte, Piso 19, Centro Simon Bolivar, Caracas, Venezuela.

Yours faithfully,

DAVID HASTINGS
Department of Geology and
Geological Engineering,
Michigan Technological University,
Michigan, USA

Nigeria needs scientific leaders

SIR,—I was interested in Lynette Hamblin's report of Professor Ekong's speech at a recent UNESCO symposium (18 January, page 168), and particularly that she considers lack of scientific leadership to be the principal reason for the low scientific output.

At the time when I left the University of Ibadan, I felt that the leadership of that university, in organic chemistry at least, was in good hands with Professor Ekong; but within a very short while he himself had left to take up university administration.

Professor Ekong is not the only leading chemist in Nigeria to have left university teaching and research for administration, in some cases at least quite unwillingly. In Nigeria there are a number of able administrators of one kind and another, whereas there are very few capable scientific leaders, and I question whether the move of scientists into administration is really beneficial, whatever may be the case in more developed countries.

Yours faithfully,

D. A. H. TAYLOR
Department of Chemistry,
University of Natal.

Soviet reactor safety

SIR,—In your report on Soviet energy (25 January, page 258) Vera Rich reports on the "accident" in BN350, the Russian fast reactor on the Caspian sea. By the use of her words "it is presented as" she seeks to imply that the "accident" was not in the steam generators and that some accident occurred in the reactor core itself. In fact, the full details of this "accident" have been known for many years in the West and have been fully reported in international conferences, for example at the 1978 Bologna Conference (D. S. Yurchenko, *et al.*, *Operating Experience with the BN 350 Fast Reactor (1972-77)*; IAEA Symposium on the Design, Construction and Operating Experience with LMFBRs, Bologna, 10-14 April 1978), and many designers have visited BN350 subsequent to the "accident".

The presentation adopted in the article in *Nature* seems likely to mislead and to cast unwarranted doubt both on the integrity of the Soviet physicists concerned, and on the safety of the fast reactor as a power generator.

Yours faithfully,

R. D. SMITH
UKAEA, Risley, Cheshire, UK

Intuitive energy figures

SIR,—P. T. Landsberg (5 April, page 502) expresses the hope that his energy figures carry an intuitive meaning. As a basically illiterate mathematician, may I say that they do. They convey the impression that Mr Landsberg wishes to encourage the belief that natural sources of energy are entirely sufficient for our needs; and that he considers it prudent to publish figures setting out the possible power yield from deserts, without demonstrating the energy investment required to achieve it.

I will gladly sacrifice the assistance of 60W bulbs per capita—even for 10⁶ joules—in the service of comprehensive energy budgets on all energy projections—illustrative or real, alternative or conventional.

Yours faithfully,

DAVID GREEN
Pembrokeshire, Wales

Nonradial and nonlinear stellar pulsation

from Douglas Gough*

IN the past two decades the theory of the pulsation of the Classical Cepheid and RR Lyrae stars has reached a high degree of sophistication. This kind of pulsation is the simplest mode of oscillation a star can undergo: it is periodic and the motion is purely in the radial direction. Although there remain some niggling discrepancies between theory and observation the agreement is sufficient to convince most astrophysicists that our ideas are basically correct. Thus we seem to have a firm foundation from which to extend our studies to stars whose oscillations are nonradial and non-periodic. In recent years considerable attention has been devoted to such stars, and last month observers and theorists who work in this field attended a workshop* at which β Cephei stars, δ Scuti stars, ZZ Ceti stars and the Sun, were discussed.

Walter Fitch (Steward Observatory) reviewed observations of variable stars of δ Scuti and related types. These stars pulsate at low amplitude, and many exhibit two characteristic frequencies which bear a ratio close to that of two small integers. Consequently much of the subsequent discussion concerned direct resonances between two modes of oscillation. Arthur Cox (Los Alamos Scientific Laboratories) reported his failure to reproduce this behaviour theoretically from initial value integrations, even when the resonance conditions had been carefully engineered, and Robert Stellingwerf (Rutgers University), who had analysed the stability of pairs of singly periodic limit cycles of potential double mode Cepheid models, never found both cycles to be simultaneously unstable to linear perturbations. The double mode behaviour remains unexplained. During discussions of parametric resonances, it was pointed out that many of these stars seem to exhibit characteristics of strange attractors. Some δ Scuti stars appear to pulsate in many modes simultaneously;

Wojciech Dziembowski (Copernicus Astronomical Centre) estimated that nonlinearities developed by any one mode alone were too small to limit its amplitude to a value as low as those observed, and concluded that mode interactions must be responsible. Definitive calculations have not yet been performed, but techniques developed for studying oceanic gravity wave interactions and plasma turbulence are available for tackling problems of this kind. We can therefore anticipate considerable advances in this study in the near future.

A class of stars for which there is no convincing explanation is characterised by β Cephei. Myron Smith (University of Texas at Austin) reviewed the observations. The stars are of spectral type B, and lie in a strip in the Hertzsprung-Russell diagram a little above the Main Sequence. Mike Jerzkiewicz (Wrocław University Observatory) and C. Sterken (Free University of Brussels) reported new observations and pointed out that almost all stars in the β Cephei strip show signs of variability. They appear to pulsate in both radial and nonradial modes. As with the δ Scuti stars simple period ratios are found, which suggest again that resonance mechanisms are operating. Frequency splitting, presumably by rotation, has been measured, which offers the exciting prospect of trying to infer the angular velocity within these stars. Unfortunately we are not yet in a position to do this because the modes of oscillation have not been unambiguously identified; different workers expressed contradictory opinions about the modes they thought were responsible for the variability.

An intriguing property of some β Cephei stars is that they switch from one mode of oscillation to another on a timescale of no longer than about 10 periods. Smith argued that this is evidence that the oscillations are confined to a rather thin outer layer of the star, because otherwise it would be difficult to envisage how dissipative processes could effect the enormous energy transfer that would be involved. Others contradicted that claim, citing simple nonlinear oscillators that can alter their character on a dynamical

timescale. It is unlikely that it will be established in the near future whether such oscillators actually represent the behaviour of β Cephei stars in any way, because the basic physics of the variability is not yet understood.

How are the oscillations driven? Morris Aizenman (National Science Foundation) reviewed the many ingenious ideas that have been proposed in the past, all of which have failed. A recent suggestion by Stellingwerf that the mechanism is no more than the Eddington valve that drives classical Cepheids and RR Lyrae stars was debated. He proposed that interpolation in opacity tables on too coarse a grid had led to an underestimate of the efficacy of the valve, but Arthur Cox, one of the chief suppliers of opacity data to the astrophysical community, claimed that though finer resolution decreased the stability of the theoretical models it was never sufficient to render them unstable. The suggestion was made that if all the mechanisms reviewed by Aizenman were operating in unison the sum of their contributions might be sufficient to maintain the pulsations against dissipation. This idea, which is reminiscent of an early suggestion for solving the solar neutrino problem, was unenthusiastically received.

Solar oscillations

A significant fraction of the workshop was devoted to discussing oscillations of the Sun. First, Henry Hill (University of Arizona) reviewed the observations spanning the period range 3^{min}–160^{min} and discussed the evidence already in the literature for the oscillations in the data being of solar origin. There followed a sequence of presentations of new observations and discussions of the longer period oscillations. Discussion concentrated mainly on two issues: the form of the oscillations in the upper atmosphere and the evidence for phase coherence.

By comparing different diameter measurements made at the Santa Catalina Laboratory for Experimental Relativity by Astrometry (SCLERA), Hill argued that the amplitudes of oscillation rise more steeply with height above the photosphere than can be

*The workshop 'Nonradial and nonlinear stellar pulsation' was organised by Professor Henry Hill and held at the University of Arizona on 12–16 March 1979. The proceedings of the workshop will be edited by Professor Hill and published in about 18 months' time by Springer Verlag in the series 'Lecture Notes in Physics'.

comfortably accommodated within the framework of linear theory. At first sight this should be no cause for alarm, because the amplitudes thus inferred in the low chromosphere are so great that nonlinearities must surely be important. Nonetheless several participants were uneasy with the result, because in the photospheric regions, where presumably linear theory is valid, the eigenfunctions have the appearance of waves penetrating an evanescent region from above yet having frequencies characteristic of the resonating cavity beneath. Tuck Stebbins (Sacramento Peak Observatory) presented measurements of relative oscillation amplitudes at different positions in the wings of a spectrum line which support Hill's conclusion, but Timothy Brown (High Altitude Observatory) found contradictory evidence from shape changes of the limb darkening function. The issue is currently unresolved.

For many people, the most convincing evidence that the oscillation data arise from genuine dynamical solar vibrations is their phase coherence. Peter Worden (Sacramento Peak Observatory) criticised early analyses of the SCLERA data, but Thomas Caudell (University of Arizona) presented new measurements of solar equatorial diameter variations which, it was finally agreed, convincingly maintained phase over an interval of 22 days. This did not terminate the discussion, however, because as Maurice Gabriel (Université de Liège) pointed out, unless there were a considerable difference in the amplitudes of eastward and westward propagating waves one would not expect phase coherence over a period longer than half the mean rotation period of the Sun. Polar diameter measurements, which have not yet been analysed, are not subject to this criticism.

One of the most exciting aspects of solar oscillations is their potential for providing diagnostics of the solar interior. To realise this potential it is essential to examine the theory quite meticulously to ensure that the physics is well understood, and that measurable properties of the oscillations of theoretical models can be computed accurately. In this respect greatest attention has been paid to the 5-min oscillations, because it is of these that the most refined measurements have been made. Investigations by groups at the University of California at Los Angeles and the Observatoire de Nice have revealed that of the uncertainties beneath the photosphere only the value of the adiabat deep in the convection zone substantially influences the oscillation frequencies; in addition, the Nice group have found that the frequencies of all but the chromospheric

modes are insensitive to variations in the structure adopted for the solar atmosphere, within the framework of the usual linearised theory. The results of both groups seem to imply that the adiabat must be that of a convection zone whose depth is at least 20% of the solar radius. This conclusion is similar to the findings of Beckers and Gilman, who reported last September at the EPS Workshop on Solar Rotation in Catania (*Publication No. 162 of the Astrophysical Observatory of Catania* (Eds Belvedere & Paternò) 1978) that they could not explain the observed absence of a polar vortex unless the depth of the convection zone were at least of the order of 40% of the Sun's radius.

The case for so deep a convection zone is not completely closed. Participants of the workshop were reminded of the EPS conference on solar physics (*Pleins feux sur la physique solaire* (Ed Rösch) CNRS, Paris, 1978) held in Toulouse last year, where Dziembowski and Pamjatnykh pointed out that the observations by Hill and Caudell (*Mon. Not. R. astron. Soc.* **186**, 327; 1979), apparently of solar g modes of degree about 30, are difficult to explain in terms of the so-called standard solar model (see *Nature*, **274**, 739; 1978). At the Arizona workshop Jørgen Christensen-Dalsgaard (Université de Liège) presented computations of g modes in a solar model with low interior heavy element abundance Z, such models have shallow convection zones through which modes of the kind reported by Hill and Caudell can penetrate with ease. Solar models with low Z also predict low neutrino fluxes in agreement with Davis's measurements, but they do pose many problems, such as how to explain the frequencies of the 5-min oscillations. Ross Rosenwald (University of Arizona) pointed out that if the claim of the SCLERA group concerning the nonlinear behaviour of the oscillations high in the solar atmosphere were correct, the linear calculations performed to date may not be relevant, and this problem may disappear. The claim has not yet been substantiated.

Another new observation which may shed light on this issue was reported by George Isaak (University of Birmingham). His group has measured variations in the Doppler shift of a sodium line in light integrated from the entire solar disk, and have measured discrete frequencies of what appear to be acoustic oscillations of low degree with periods of about 5 min. Unlike the most common 5-min modes, these penetrate beneath the convection zone,

Douglas Gough is in the Department of Applied Mathematics and Theoretical Physics, University of Cambridge, and is at present at the Observatoire de Nice.

and provide an integral measure of the structure deep in the solar interior. A preliminary theoretical analysis favoured a model with a somewhat lower value of Z than that of the standard model, and a shallower convection zone. This model lies between the two extremes discussed above, and so serves to remind us how uncertain we are of the Sun's internal structure.

Degenerate variables

The final day of the meeting was devoted to degenerate variables. Edward Robinson (University of Texas at Austin) gave a stimulating review of the observations, many of which have been obtained only in the past few years. Most of these variables appear to be DA white dwarfs lying in a narrow range of spectral type with $B-V \approx 0.2$, though John McGraw (University of Arizona) in particular has observed variable white dwarfs of different colours. Of the DA dwarfs, about 25% are observed to be variable, and aside from their variability show no other distinguishing feature. Luminosity amplitudes range from a few tenths of a magnitude down to the limit of detectability.

The low amplitude variables have stable periods; one such star, R548 is even more stable than the Crab pulsar. The larger the amplitude the longer the period, and the less stable the power spectrum of the pulsations. It is not unusual for the stars with larger amplitudes also to switch entirely from one mode to another.

Oscillation periods range between about 100 s and 1,000 s, which are much too long to be p modes. Explanations in terms of g modes have been attempted, but it is sometimes difficult to fit the periods satisfactorily. Moreover, with the longer period variables it is difficult to explain why neighbouring g modes in the densely spaced spectrum are not observed, a problem faced also by those who argue that the 2^h 40^{min} oscillation of the Sun is a g mode. Carl Hansen (Joint Institute for Laboratory Astrophysics) suggested that perhaps the oscillations were toroidal elastic modes of a rather mushy material, but reliable estimates of the elastic properties of these degenerate stars are not available to test this hypothesis. In any case it was difficult to explain why only oscillations of the periods observed should be driven, and the others damped. Arthur Cox pointed out that (with the eye of faith) one could imagine the region in the HR diagram where pulsating white dwarfs have been found to be an extension of the classical Cepheid instability strip. He found models that were unstable to radial pulsations, but the periods of such modes are only about 1 s. □

More reliable counts of chromosomal aberrations

from John R. K. Savage

A NOVEL application of a staining method widely used to identify newly-synthesised DNA to the problem of obtaining reliable dose-response curves for the effects of radiation damage in cells is reported in this issue of *Nature* (page 756). The number of chromosomal aberrations induced per cell is the usual measure of radiation exposure. But the precise correlation of dose with the number of chromosomal aberrations it produces is complicated by (amongst other factors) the difficulty of differentiating between cells which have divided a second time after treatment and before analysis. The inclusion of these second division cells in the total cell count inevitably leads to an underestimate of the number of chromosome aberrations produced by any given dose, as the probability of any cell's surviving a second division decreases the larger the number of aberrations it carries. Thus there is selection for less-damaged cells which dilute the scoring sample and reduce the observed yield of aberrations per cell. In a desynchronising cell population like the *in vitro* blood lymphocyte system, the contamination by second and subsequent division cells will increase progressively with time from initiation and a concomitant fall in the yield of asymmetrical aberrations will be observed.

John R. K. Savage is Head of the Cytogenetics Department, MRC Radiobiology Department, Harwell.

In the past, many workers, aware of this problem, have sampled as early as possible after stimulation, on the principle that the earliest samples are purer first divisions. In practice, a compromise is made to ensure that a sufficient number of mitoses for scoring is present, and for human lymphocytes a time ~48 h after exposure is usually chosen. Even at this time, second division contamination may not always be negligible and careful workers attempt a further purification of this sample by omitting from their score cells with obviously modified aberrations or those lacking a full complement of acentric fragments.

Now, as Scott and Lyons elegantly demonstrate (page 756) application of the FPG 'harlequin' technique goes a long way towards solving this problem. The technique provides differential staining of the chromatids in second and subsequent division cells based on the semi-conservative segregation of bromodeoxyuridine incorporated in the DNA during synthesis phase. Consequently, by confining scoring to cells with chromosomes not showing differential staining, only first post-treatment division cells will be included in the sample, irrespective of sampling time. As Scott *et al.* show, the asymmetrical chromosome-type aberration yield induced in these cells by 200 rad X-rays is constant, independent of sampling time over the range of 40-72 h. This supplies some evidence for the homogeneous radiosensitivity of

the initial population, and provided the constant yield holds for other doses (which seems to be the case from our own preliminary work), the form of dose-response curves obtained with this method should be much more consistent than hitherto. No enhancement of aberration yield was recorded at the concentration of bromodeoxyuridine used or from its method of application. There was, however, a concentration-dependent perturbation of cell progress, but this has little relevance if the primary population is really homogeneous.

The technique is essentially very simple to apply, and there is no reason why it should not be routinely used in all future dose-response curve work. When one considers the tremendous mathematical effort which goes into the fitting and parameter derivation from such curves and their interpretation, it is surely worth-while to ensure that they have a reliable shape before starting.

The advantages of the method are not confined to dose-response curves; one can see many applications in the field of chromosomal aberration studies. For example, in the study of chromosomal mosaics (individuals whose tissues contain mixtures of two or more karyotypically different cell types) the observed relative frequencies of the cell types are in many cases influenced by selection at cell division. Confining scoring to first division cells may help towards reducing the between-sample variability frequently found.

Are protons unstable?

from F. E. Close

THE experimental lower limit on the proton lifetime is well over a trillion times the age of the Universe and this has led people to believe that the proton is indeed absolutely stable. Recent theoretical attempts to construct theories that unify the strong force with the weak-electromagnetic force (see *Nature* 277, 349; 1979), however, have the consequence that the proton is not absolutely stable. A lifetime as 'short' as 10^{31} years could be possible (about an order of magnitude greater than the present lower limit).

Quantum electrodynamics (QED) and quantum chromodynamics (QCD) (the theory of the strong interaction) are very similar field theories and appear in many ways to be profoundly and intimately related. Recently devel-

oped ideas on grand unification of the natural forces do just this and postulate that they are related in a way that is made precise by group theory. Mathematically, QED is a U(1) field theory and QCD is an SU(3) ('non Abelian') field theory, the U(1) essentially displaying the fact that there is but one kind of electrical charge (which can be positive or negative like the set of real numbers) and the SU(3) displaying the existence of three kinds of colour charge (often called red, yellow and blue by analogy with the primary colours). In a nutshell, QCD is like QED with 3×3 matrices in place of real numbers in the 'photon' (coloured gluon) couplings. (Photons are the quanta of the electromagnetic force; coloured gluons those of the strong interaction.) To unify these, find a group G which contains $SU(3) \times U(1)$

a possible source of proton decay

and postulate that there exists a corresponding field theory. The SU(3) QCD and U(1) QED will then be two particular subclasses of this grand field theory. Unification of QCD with the electromagnetic and weak interaction can be achieved if G is the group SU(5) or SO(10). A consequence of this unification is that at energies typical of the world about us the SU(3) colour force is stronger than the U(1) electromagnetic. This is in accord with observed atomic structure: the protons and neutrons (quark systems) are bound in the nucleus by the strong force while the electron (lepton) orbits the nucleus at large distances held by the electromagnetic force.

An outcome of such a unification is that in addition to the photon and the

F. E. Close is at the Rutherford Laboratory.

coloured gluons of QED and QCD, there will exist a new ultraweak force whose quanta carry and couple both to electrical and to colour charge. These quanta have been called 'leptoquarks' because they have the remarkable property of being able to cause quarks to change into leptons, and hence to make the proton decay.

Leptons and quarks are very similar, the only essential difference being that quarks have colour whereas leptons do not. Imagine the effect of a leptoquark quantum being absorbed by a lepton (the electron for example). The leptoquark couples to electrical charge and so can fuse with the electrically charged electron. But the leptoquark also carries colour and so 'paints' the electron transforming it into a quark. The leptoquark quanta carry electrical charge which are fractions of an electron charge so the quark produced from the lepton will have fractional charge, as it must.

Just as electrons could be turned into quarks so could quarks decay into leptons, and this is the source of the predicted instability of the proton. The specific nature of the predicted decay products tends to be rather dependent on the particular model under consideration. In the SU(5) scheme a final state of an antilepton (positron, e^+) and neutral pion (π^0) is predicted and seems to be the one most widely favoured by theorists. The way that this happens is illustrated in the figure and is due to the predicted leptoquark quantum, X. This has electrical charge $4/3$ and can transform a u(up) quark (charge $2/3$) into an antiup ($\bar{u}$) of charge $-2/3$ on being emitted. Absorbed by a d(down) quark of charge $-1/3$ it produces an antilepton (e^+) of charge $+1$. Colour and electrical charge are conserved throughout and the proton (two up quarks and a down) decays into $u\bar{u}$ (π^0) and e^+ at a rate of 1 in about 10^{31} to 10^{33} years.

Experiments that may be sensitive to such decays are now being planned and one is already underway in Montana, USA. If one hopes to detect at least 1 such decay per year then over 10^{21} protons are needed for study, hence over 3,000 tons of material are called for. The cheapest is water and typical experiments plan to have a large swimming pool of about 20 m in each direction, built deep underground to reduce cosmic ray backgrounds. Deep mines are one possibility and in Europe the Mont Blanc tunnel (on average 3,000 metres below 'ground') has been suggested. Detectors of Cerenkov radiation are needed; the signal being some 500 MeV of radiation detected in one direction in coincidence with 500 MeV in the opposite direction. One set will be from the antilepton in the proton decay, the other will be from

the π^0 (this having decayed into two photons which in turn produce electron-antielectron pairs, these latter giving rise to the Cerenkov light).

There are many technical experimental problems to be overcome but the idea seems feasible and the stakes are high. Typically two years preparation and three years experimentation may be involved. However, the experiment currently in progress in the USA may be sensitive to about 10^{31} years' lifetime and could produce results in a year or so. If the lowest theoretical estimates are correct then we may soon have evidence for proton decay. □

Adsorbates on transition metals

from Marvin L. Cohen

THE recent renaissance in surface science has been motivated partly by a desire to explain and exploit the catalytic properties of d-electrons near transition metal surfaces. However, many technologically relevant problems connected with catalysis were put aside to await reproducible experiments and extensions of theoretical techniques which could deal with the properties of clean surfaces and surfaces with adsorbates. Experimental developments over the past 5 years in high vacuum science, photoelectron and electron loss spectroscopy, and low energy electron diffraction have provided accurate data. On the theoretical side, very recent progress has produced calculated spectra suitable for comparison with experiment, but much of the theoretical emphasis has been on semiconductors (Appelbaum & Hamann *Rev. Mod. Phys.* **48**, 3; 1976; Schlüter, Chelikovsky, Louie & Cohen *Phys. Rev. B* **12**, 4200; 1975) where the electronic states of interest have not been d-states.

The semiconductor research has provided convenient tests of the theory. One major point has become clear. A surface is not just the undeformed edge of a perfect crystal. Rearrangements take place, and the electronic charge distorts in response to the surface perturbation. The readjustment of the electronic charge density causes a change in the electrostatic potential felt by the electrons near the surface. This change has to be included in the theoretical calculations. This is done through a self-consistent or feed-back technique. The electronic charge density is calculated for an ideal surface, and the change in the potential arising from the surface redistribution of charge is fed back through the potential to produce a new charge density. This

Fig. 1 Comparison of the calculated H-induced photoemission difference spectra with the experimental difference curve from Demuth *op. cit.*

is repeated until the input and output charge densities agree. When the calculation is self-consistent, the detailed surface properties can be examined. Many surface properties are determined by electronic surface states which are found localised near the surface. The surface states are affected by adsorbates, defects, steps and the detailed crystal structure of the surface. Self-consistent calculations for semiconductors have yielded a significant amount of information about these cases.

For transition metals, difficulties in handling the localised d-electrons have resulted in slower progress. However, S. G. Louie (*Phys. Rev. Lett.* **42**, 476; 1979) has recently completed the first fully self-consistent calculation for the electronic structure of an adsorbate on a transition metal. His work focused on the interaction of hydrogen with the Pd (111) surface. This calculation should serve as a model for future adsorbate studies on d-band materials. It also provides useful information for hydrogen-storage technology.

Louie's calculation is based on a self-consistent pseudopotential approach. The pseudopotential is an effective potential which determines the electron-ion interaction in the crystal. The self-consistency allows for charge readjustment at the surface and for charge flow between the adsorbate and the transition metal. This approach had already been used successfully for three studies of clean transition metal surfaces, Nb (001) (Louie *et al. Phys. Rev. B* **15**, 5627; 1977), Pd (111) (Louie *Phys. Rev. Lett.* **40**, 1525; 1978) and Mo (001) (Kerker, Ho & Cohen *Phys. Rev. B* **18**, 5473; 1978). The new extension which adds the hydrogen adsorbate uses the clean surface results

FLOWERS provide nectar for bees, and in return a bee acts as a kind of flying penis, carrying pollen from one plant to fertilise the ovaries of another. Plants and their pollinators are a classic example of mutualism: they have coevolved through evolutionary time in a reciprocal beneficial relationship. However this superficially harmonious view may conceal the true nature of the interaction. It is perhaps more accurate to think of bees having evolved towards efficient exploitation of plants as a food source, while plants have evolved adaptations to minimise the price they pay for getting bees to transfer pollen. G. H. Pyke (*Oecologia* 36, 281; 1978) has used this line of argument to develop a new insight into the structure of certain inflorescences and the foraging behaviour of bees. He studied three plant genera *Delphinium*, *Aconitum*, and *Epilobium*, all of which are cross-fertilised by bumblebees (*Bombus* spp.), and have their flowers arranged in a vertical spike.

Bumblebees feeding on these plants follow a characteristic movement pattern. They almost invariably start at the bottom of an inflorescence, move up the spike, and leave to fly to the next plant before reaching the top. Within the inflorescence, a bee typically moves vertically upwards from one flower to the nearest one above. The flowers of all three plant genera are arranged in a spiral around the vertical spike, so that by moving vertically upwards, a bee misses out some of the flowers. The bees' movement rules are related to nectar availability. Flowers at the bottom of an inflorescence are older, bigger and contain more nectar than those at the top, hence by starting at the bottom the bee visits the most profitable

Coevolution of bees and flowers

from John R. Krebs

flowers first. As it moves up the inflorescence the bee experiences gradually diminishing returns from the successively smaller flowers, until there comes a point at which more nectar per second could be obtained by travelling to the bottom of the next inflorescence. Pyke's measurements suggested that bees roughly follow this optimal departure rule, and this accounts for the fact that a bee usually leaves before reaching the top of an inflorescence. At first sight one might think that it would pay the bee to visit every single flower on its way up the inflorescence, rather than missing nectar-rich flowers near the bottom. However, the spiral arrangement of flowers reduces the benefit of this movement rule. The extra energetic costs to the bee involved in manoeuvring sideways to follow a spiral path more than offset the benefit of visiting all the flowers. The rule of moving straight upwards gives a higher net energy gain.

Bumblebees seem to have evolved a set of rules for efficient exploitation of nectar, but the plants are equally under an evolutionary pressure to exploit bees, and Pyke suggests that the flower arrangement can be interpreted in this way. The larger, older, nectar-rich flowers at the bottom of an inflorescence are female, while the younger flowers at the top are male (the plants are protandrous hermaphrodites, meaning that each flower turns from male to female as it gets

John R. Krebs is in the Edward Grey Institute of Field Ornithology, University of Oxford

older). This arrangement of flowers ensures that a visiting bee arrives at the female flowers near the base having just come from the male flowers near the top of the previous plant. In this way the chance of outcrossing is increased, and it is known that in *Delphinium* at least outcrossing results in a higher percentage seed set (Price & Waser *Nature* 277, 294; 1979). The spiral arrangement of flowers around the stem is also important to the plant. A bee does not usually carry enough pollen to fertilise all the female flowers on a plant, so if it visited every flower it would extract some nectar without providing pollen in return. The plants' evolutionary answer seems to be to arrange its inflorescence in such a way that an efficient bee actually does better by missing some of the female flowers.

Given the design of plants, bumblebees seem to approximate an optimal set of movement rules for maximising net rate of harvesting nectar. At the same time the plants have evolved a design which makes highly efficient (perhaps optimal, but not enough is known about benefits to plants) use of bees as pollinators. It might appear that the coevolutionary struggle has reached a stable point where bees and plants are doing as well as they can, but there is another aspect to the problem. Different species of plants (as well as different individuals of the same species) compete to attract pollinators, and a complete account of the coevolution of bees and plants must be able to explain why different plants living in the same area are designed to offer nectar in different ways. The answer to this sort of question may emerge from approaches such as Pyke's.

for comparison to determine the changes caused by the adsorbate.

A convenient way to explore the effects of the adsorbate is to calculate the surface density of states with and without the adsorbate and to examine the difference in these two functions $\Delta N(E)$. Since the density-of-states function determines the number of electronic states in each energy interval, surface or adsorbate states show up as peaks in this function in the energy interval corresponding to the binding energy of the state. The difference function $\Delta N(E)$ demonstrates how the states near the surface are affected by the adsorbate.

The site where the hydrogen atom is adsorbed on the Pd (111) surface isn't known, but three different sites are likely. Louie's calculation models all three sites (A, B and C) and computes the $\Delta N(E)$ function for each case

(Fig. 1). This function can be compared with a difference photoemission spectrum (Demuth *Surface Sci.* 65, 369; 1977) to determine which geometry fits the measured results.

One prominent feature common to all the $\Delta N(E)$ curves is the dip near the metal Fermi energy (0 eV). This dip reflects the adsorbate correlated movement of states away from this region to lower energy. The peaks at lower energies arise from the new hydrogen induced states formed from hydrogen 1s and Pd d-states. Comparison of the $\Delta N(E)$ spectra rules out site A and favours B and C which differ little in their environment. Louie concludes that the hydrogen atoms prefer a threefold hollow over the top site. This geometry yields an occupied H-Pd bonding surface band centred at 6.5 eV below the Fermi energy (Fig. 1) in good agreement with experiment

and an unoccupied antibonding H-Pd surface band at high energies (not shown in Fig. 1). Other surface structure is found and analysed.

The features of the H-Pd bonding state can be studied using charge density contour maps. These illustrate the details of the mixing between the hydrogen and Pd orbitals. Louie has also calculated the total electronic charge distribution and finds that some charge spills out into the vacuum above the surface. The values for the number of valence electrons per surface unit cell are 0.2 in the vacuum above the surface and 9.7, 10.1, 10.0, 10.0 for the first, second, third and fourth layers into the bulk (10 is the bulk value). The calculated work function is in excellent agreement with experiment.

Although Louie's calculation only considers a specific adsorbate on a specific face of one transition metal,

his success in getting information about the adsorbate site and bonding configurations provides strong motivation for future studies. The next level of complexity would be studies of molecular adsorbates (for example CO) on different surfaces of a variety of transition metals. Calculations of this kind should be possible soon, and theoretical results on systems like these should provide useful data for understanding surfaces and for developing new catalysts □

Surface structure by SEXAFS

from D. T. Clark

THE wide variety of techniques which have been developed to take particular advantage of the special characteristics of synchrotron radiation have previously been notified in these columns and (*News and Views* 276, 672; 1978) span fields as diverse as the band structure of metals and the study of time-dependent conformational changes for proteins. The benefits of having a dedicated synchrotron source as opposed to operating in parasitic mode to basic high energy physics experiments has been appreciated for some time in the UK and in consequence a national facility is currently nearing completion at SRC's Daresbury Laboratory. It is already clear from the published work, particularly of a number of research groups in the USA, that synchrotron sources will have a vital role in surface science in particular. The benefits of a highly collimated, continuous spectrum which includes wavelengths not available from other sources is self evident in the investigations of structure and bonding of the surfaces of solids since differential changes in photoionisation cross sections and different sampling depths (consequent upon the strong dependence of electron mean free paths on kinetic energy) are thereby routinely available.

In addition, however, there are three properties of synchrotron radiation sources which enhance their potential for research in surface science. First since the electron beam is extremely stable in energy, position and intensity the light-emitting areas are endowed with the same characteristics. Second the substantial degree of polarisation of the photon source after monochromatisation provides a means of studying

asymmetry parameters and channelling phenomena and finally since the synchrotron source typically operates in the UHV regime there is direct compatibility with the requirements for carrying out experiments on uncontaminated surfaces.

The experiments which have so far been carried out in the area of surface science have largely centred on the investigation of the valence bands of metals and semiconductors and this has been a fruitful area of research particularly in the US in the research groups of Eastman, Spicer and Shirley.

In an important paper recently appearing in *Phys. Rev. Lett.* (42, 104; 1979) Bianconi and Bachrach have shown for the first time that measurements of surface extended X-ray absorption fine structure (SEXAFS) provides a powerful alternative to LEED in the investigation of surface geometries of single crystals. This obviously extends the scope of synchrotron radiation in the investigation of surfaces and it is worthwhile briefly considering the background to this work.

The basis of EXAFS, in particular as it relates to the investigation of metalloprotein systems, has recently been considered in these columns (*News & Views* 277, 89; 1979) and one need only note that previous theoretical proposals relating to the use of SEXAFS have now been implemented in the paper described here. The important question of the structure determination of surfaces have until now been addressed by one technique only, namely low energy electron diffraction (LEED). The technique is limited to single crystal analysis and the investigation of chemisorbed atoms or molecules with long range order and has relatively poor resolution. Despite the difficulties in theoretically modelling the experimental data the technique has provided important data which illustrate for example the reconstruction (change in interatomic distances) for most semiconductor surfaces.

LEED experiments on Al (100) and Al (111) surfaces have previously been reported (Martin & Samorjai *Phys. Rev.* B7, 3607; 1973; Jepson, Marcus & Jona *Phys. Rev.* B6, 3684; 1972; 5, 3933; 1972) and have been interpreted in terms of no reconstruction for the former and a 5–10% increase in interatomic spacing for the latter face. Since LEED typically provides a resolution of ~ 0.1 Å there is clearly some ambiguity in interpreting small changes in spacings. By contrast Bianconi and Bachrach demonstrate that the substantially higher sensitivity (with respect to spacing) of the EXAFS measurements allows an unambiguous assignment of both the sign and magnitude of the restructuring of the Al

(111) surface compared with the bulk.

The experiments described by Bianconi and Bachrach involved measuring the quantum yield of secondary electrons originating from inelastically scattered LVV Auger electrons generated in the decay of the absorption produced core holes. Using this partial yield technique measurements may be made of the $L_{2,3}$ surface soft X-ray absorption spectrum of a surface layer of aluminium single crystals; the thickness being determined by the effective escape depth of the secondary or Auger electrons with the selected kinetic energy.

The experiments were carried out on the grazing incidence monochromator fitted to the 4° beam line at the Stanford Synchrotron Radiation Laboratory. The photoelectron energy was selected with a cylindrical mirror analyser (detection cone at $\theta=42^\circ$) using a 3 eV window. The linearly p polarised light was incident near grazing ($\theta \leq 10^\circ$) and this strongly emphasises the interatomic distance normal to the surface. The Al single crystals were cleaned by ion sputtering and annealing at 4×10^{-10} Torr and in separate experiments the residual oxygen contamination was shown to be < 0.001 monolayer.

Surface soft X-ray absorption spectra of the Al (100) and Al (111) faces were measured collecting the inelastically scattered Auger electrons at 45 eV and 4 eV. At 45 eV final state energy an average of ~ 2.9 Å thick layer contributes to the spectrum which corresponds effectively to the surface layer since the interatomic spacing is 2.86 Å for the bulk metal. For a 4 eV final state energy the escape depth is closer to 20 Å so that *a priori* one might expect a comparison with data for the bulk. Structural information is extracted from this data by fitting the first large EXAFS modulation. The almost exact correspondence of the data for bulk aluminium and for the Al (100) surface shows conclusively that within the limits of the experiment there is no restructuring for this surface. By contrast the fact that the EXAFS structure shifts towards higher energy on going from bulk to surface shows directly that for the Al (111) face there is a decrease in interatomic spacing. By using the bulk aluminium EXAFS as reference this contraction may be quantified as $\Delta r = 0.15 \pm 0.05$ Å.

These experiments confirm the great potential of SEXAFS in the investigation of the surface structure of single crystals and it will be of interest to have comparisons with LEED data on other materials for which surface restructuring has been inferred. It should be noted that SEXAFS can also in principle be applied to the study of amorphous surfaces and we may antici-

pate that the technique will be extensively applied to such materials over the next few years. $\square$

Nuclear giant dipole resonance

from P. E. Hodgson

LONG ago it was found that the cross sections of many reactions of gamma rays with nuclei, in particular those in which a nucleon is ejected, show broad resonances at quite high energies, usually around 20 MeV for light nuclei and falling to about 10 MeV for heavy nuclei. It was soon suggested that these resonances are due to a special type of collective excitation in which the neutrons vibrate against the protons. The resonance was found to be E1 (electric dipole) and a macroscopic calculation based on the liquid drop model gave approximately the correct variation of resonance energy with atomic weight.

Subsequently, detailed microscopic models have been developed that interpret the resonance as due to the coherent superposition of all possible particle-hole excitations from one major shell to the next. This was able to account for the width and the energy of the giant dipole resonances in several light nuclei.

The macroscopic models in terms of neutron and proton fluids were also developed, and these have the advantage that they give results for a whole range of nuclei for which the microscopic calculations would be very complicated. The most detailed of the macroscopic models are first that of Goldhaber and Teller (*Phys. Rev.* 74, 1046; 1948), which assumes that the oscillations of the neutron and proton fluids each take place within a fixed boundary, and this predicts that the excitation energy varies as $33 A^{-1/6}$. A second model, due to Steinwedel and Jensen (*Z. Naturforsch.* 5A, 413; 1950) assumes that the neutron-proton

oscillation takes place within one fixed boundary, and this gives $80 A^{-1/3}$ for the energy dependence. More recently, Myers and Swiatecki (*Phys. Rev.* C15, 2032; 1977) have developed a more detailed theory based on their droplet model of the nucleus, and this gives an energy variation of $A^{-1/2}$, which is nearer to the experimental results than the other models. The models also predict distinctly different transition charge densities.

To test these models, Pitthan and colleagues at the Naval Postgraduate School, Monterey, California have recently made some careful measurements of the inelastic scattering of electrons by ^{140}Ce (*Phys. Rev. Lett.* 41, 1276, 1978). This nucleus was chosen because of all the nuclei investigated it shows the most favourable separation between the various possible resonances. The spectrum of inelastically scattered 91.2 MeV electrons that they obtained is shown in Fig. 1, with the background already subtracted. A number of peaks are visible, corresponding to the electric resonances of various multipolarities. The spectrum is analysed into the contributions from the different multipolarities, and the one of interest for distinguishing between the different models is the dipole resonance at about 15.3 MeV. Similar measurements were made at a number of incident electron energies from 65 to 150 MeV.

The results for the dipole resonances at different electron energies were compared with the models of the excitation process by plotting the ratio of the experimental cross section to the Mott cross section at a particular angle as a function of the momentum transfer, and this is compared with predictions of the three theories in Fig. 2. It is clear that the Myers-Swiatecki model agrees very well with the data, whereas the Steinwedel-Jensen model predicts cross sections that are too high.

The Goldhaber-Teller model predicts cross sections that are too low, but it is just possible that the shortfall could be attributed to the presence of an undetected monopole (breathing mode) resonance. This state, in which the nucleus oscillates radially, has been predicted theoretically, and some evidence for its presence has been found in previous experimental work (see for example *News & Views* 271, 212; 1978). To study this possibility, the difference between the predictions of the Goldhaber-Teller model and the experimental results was compared with distorted wave calculations of the contribution to be expected from a monopole excitation. The overall dependence

Fig. 2 Comparison between the experimental results of the electric dipole resonance at several values of the momentum transfer and the predictions of three theories of the excitation process.

on momentum transfer is found to be the same, and if it is indeed monopole it exhausts about 45% of the energy-weighted sum rule. This interpretation is however doubtful partly because the variation with A is already in disagreement with the Goldhaber-Teller model, and partly because if the monopole interpretation is correct we would expect to see all the energy-weighted sum. Thus at present the evidence favours the Myers-Swiatecki model for the giant dipole resonance. In addition, there is some discrepancy between the evidence in favour of the monopole state obtained from measurements of inelastic alpha-particle scattering and its absence in the more thoroughly understood inelastic electron scattering. Further measurements of both electron and hadron inelastic scattering are needed to resolve this discrepancy. $\square$

Physics in archaeology

from Robert Hedges

TRADITIONALLY, Archaeometry Symposia focus on the development and application of physical methods to archaeology, and there were no papers on environmental or biological issues, although two studies on the survival and extraction of organic residues were presented. Broad categories, often leading to parallel sessions, of dating, prospection, artefact analysis with the aims both of reconstructing ancient technologies, and determining the original point of manufacture, and mining and extractive metallurgy continued to provide the bulk of the research reports.

Fig. 1 Spectrum of 91.2 MeV electrons inelastically scattered from ^{140}Ce at 90° , showing the peaks due to the electric resonances of the multipolarities indicated. This spectrum is analysed into its components.

P. E. Hodgson is a Lecturer in Nuclear Physics in the University of Oxford.

*The 19th International Symposium on Archaeometry and Archaeological Prospection was held on 28-31 March in London.

Dating was emphasised by the presentation of three longer reviews, outlining recent progress. D. Walton (University of Oxford and McMaster University) described the measurements made of the strength of the Earth's magnetic field from small samples taken from dated Greek pottery, using a SQUID magnetometer. The resulting curve shows rapid fluctuations in the field strength which, apart from their general interest, he pointed out might eventually be useful for precise dating. This account was nicely contrasted by one from J. Pilcher (University of Belfast) who reviewed the latest story on radiocarbon calibration. Here the rapid fluctuations ('wiggles') in the calibration curve have been a source of contention for several years, but it seems that, with the development of more accurate measurements, an honourable compromise is being reached. The new possibilities opened to radiocarbon dating through the development of detection by accelerators were also reviewed. Several papers were devoted to the dating of calcitic cave deposits from the disequilibrium found in the daughter products of uranium incorporated into the calcite. This approach, which bridges the gap between postassium/argon and radiocarbon dating, is clearly becoming more useful. Technical papers on thermoluminescence dating of pottery, flint and calcite showed that the time when it can provide a problem-free dating service is still some way off. The same also applies to dating by amino acid racemisation.

Research into prospection methods has diminished somewhat over the years, most papers being application reports or describing advances in data-processing techniques. The analysis of artefacts remains a very strong centre of interest, however. The sourcing of such raw materials as jade, obsidian, sanukite, marble, as well as pottery and glass, from measurements of characteristic trace element concentrations (usually by neutron activation) and also of stable isotope ratios were described. The relationship of metal composition to the parent ore also was the subject of discussion, since the smelting process, and especially the addition of fluxes, can complicate this. Fortunately the excavation of mining sites, such as the Bronze Age site of Timna (in the Negev), in which ore, slag, smelted metal and artefacts are all available for study, can add much information to a perennially-disputed area. Although no radically new method or material for determining provenance has been introduced, the quality of work now able to exploit the general principles

Unified theories?

THE analogy to Maxwell's unification of electricity and magnetism and the so-called 'unified' theory of weak and electromagnetic interactions expressed in F. Close's report in *Nature News and Views* 277, 349; 1979) "an intellectual achievement comparable with Maxwell's unification of electricity and magnetism", is an overstatement. Because however this statement is amply and repeatedly expressed in all journals, and even in the general press, it should be emphasised that the latter theory is not a unified theory on the level of Maxwell's unification. There are two coupling constants G and e of the weak and electromagnetic interactions before the 'unification', and there are still two coupling constants (parameters) after the 'unification', only mixed. Moreover, a large number of new (unobserved) fields are introduced here, but not in Maxwell's case. Two

F. CLOSE REPLIES: In his book 'The First Three Minutes' Weinberg writes: "A field theory which *unifies* [my italics] (weak and electromagnetic) forces was proposed by myself . . . and Salam". It is the continuing accumulation of data supporting this theory that leads me and others to be so optimistic about it. On the other hand I recognise that there are important predictions that are as yet untested, hence my reference to it still as a candidate theory.

If the theory is eventually confirmed to be truly unified (in the sense of involving only one coupling constant,) then I would regard that as an achievement comparable to Maxwell's. That is a personal opinion which Professor Barut might not share. However he is correct to remind us that the *unification* (as defined above) is not yet confirmed

general observations may be made.

(1) Given any two theories, one can always consider them together as part of a larger more symmetric system, if enough new fields (such as gluons, Higgses) are introduced. It is like putting any two broken shapes into a larger more complex or symmetrical figure if enough clay and glue is introduced. (2) A theory is the more renormalisable the more fields are present to cancel the divergences.

Under these circumstances gauge theories can be called unified field theories only if and when all these additional hypothetical gluons and Higgses are found and if there is only one coupling constant. Until then all so-called 'evidence' must remain circumstantial and we should call them simply gauge theories and not unified theories.

A. O. BARUT

International Centre for Theoretical Physics, Trieste

even though no evidence against it has yet been found. The unified theory predicts that charged and neutral weak radiation exist and the corresponding quanta are $W^\pm$ and Z bosons with well defined masses. Just as the prediction of electromagnetic radiation was pivotal in electromagnetic theory so are the predictions of the masses of the weak quanta significant tests for the unified theory.

It is true that the properties of the Higgs fields are as yet unclear but I think that Professor Barut exaggerates by claiming that a "large number" of new unobserved fields are introduced. The inclusion of gluons in his list is particularly misleading. These have nothing to do with the weak-electromagnetic unification but are instead the gauge fields of QCD—the candidate theory of the strong force.

already established has considerably improved.

The original technical divisions of archaeology into Stone, Bronze and Iron Ages have become greatly refined as a result of more subtle studies of the materials manufactured in antiquity. Most studies centre on the interpretation of chemical analytical data, generally obtained by non (or minimally) destructive methods. These are enhanced by such sophisticated techniques as ESR, and Mössbauer spectrometry, from which, for example, information about the firing conditions of pottery, and possibly subsequent weathering on burial, is obtained. Several papers were given on coin analyses, as well as considerations on distributions of coin dies. The study of ancient metallurgy bene-

fits greatly from the information available from metallography. Thus we were able to consider how much the workers of Early Dynastic Egypt knew of the work-hardening properties of their copper tools, and how much Mediaeval armourers understood of the tempering properties of their steels. Modern experiments with reconstructed bows have confirmed theories of armour-piercing, and show that Mediaeval craftsmen, while perhaps not aware of the theory, nevertheless achieved optimum design in practice.

The overall impression left was of an encouraging increase in the quality of work presented. On the whole the archaeology considered was more appropriate and interpretations better judged. □

review article

The use of high energy accelerators in the nuclear fuel cycle

P. Grand

Department of Nuclear Energy, Brookhaven National Laboratory, Associated Universities Inc., Upton, New York 11973

Nuclear power is at present derived from the burning of ^{235}U which constitutes about 0.7% of the natural uranium resource. A long-term supply of nuclear fuel for electrical power generation would require breeders to convert ^{238}U , or ^{232}Th , into fissile material. Accelerator breeders offer an alternative to the fast breeder reactor for this conversion.

THE nuclear-power industry in most of the world is based at present on light-water-cooled thermal reactors (LWRs) either of the pressurised water or the boiling water type. These reactors have proved to be reliable and economical; they supply more than 10% of the electric power generated in the US. In the present nuclear-fuel economy, LWRs burn naturally occurring fissile uranium (^{235}U) concentrated to about 3% of the total fuel volume; the remaining fuel consists of the element ^{238}U . Isotope ^{238}U is called 'fertile' because it can be converted to fissile plutonium (^{239}Pu) which can then be used as a nuclear fuel; thorium (^{232}Th) is also fertile. Conversion from fertile to fissile material is accomplished by neutron capture in fertile nuclei. Thus, in simplified form,

This conversion occurs in every reactor. LWRs have a conversion ratio (fissile material created to fissile material burned) of about 0.6. If this ratio can be made larger than 1, the reactor breeds: it produces more fuel than it burns.

Natural uranium contains only 0.7% fissile ^{235}U , the remainder being ^{238}U . To achieve the ~3% ^{235}U concentration required for LWR fuel, mined uranium is processed in an isotopic separation plant. About 6 tonnes of natural uranium are required to produce one tonne of fuel at 3% concentration. The remaining 5 tonnes, still containing about 0.2% ^{235}U , accumulate at separation plants as waste. The 1 tonne of 3% enriched uranium produces about 2.3×10^6 kWh of electrical energy ($30,000 \text{ MW d}^{-1} \text{ tonne}^{-1}$ (thermal)) in an LWR.

If we assume the useful life of a 1,000 MW(e) nuclear reactor to be 30 yr, its fuel requirements will be about 6,000 tonnes of natural uranium over that period, of which only 1,000 tonnes will go through the reactor burn cycle and end up as spent fuel. Spent fuel still contains ~2% fissile material, about half of which is plutonium and the remainder unburned ^{235}U . Approximately 30% less fuel would be needed were the ^{239}Pu recovered from the spent fuel by chemical reprocessing.

The natural uranium resource in the US has been estimated to be anywhere from 1.5 to 4 M tonnes (refs 1, 2). These estimates include uranium which can be recovered at a cost of less than \$30 per pound of yellow cake (U_3O_8). This resource can only support 250,000–600,000 MW(e) respectively of nuclear power generation capacity based on present once-through LWR fuel cycle. Domestic resources in the US would be sufficient to supply this country's foreseeable power needs well into the twenty-first century using only the once through LWR cycle. However, many other countries, having little or no uranium resources, are not so fortunate. Therefore, the present generation of LWRs, operating on the fuel cycle described here, is not a long-term solution to the world electrical energy problem.

The development and commercialisation of the breeder reactor has been described as the answer to the full use of the world's

Fig. 1 Nuclear reactions produced in the accelerator breeder target.

uranium resources. As the breeder reactor has a breeding ratio greater than 1, essentially all the naturally occurring fertile ^{238}U in the fuel element could be rendered fissile while at the same time power was produced. Using the breeder reactor, the uranium fuel resource could be extended 100 times, and with higher priced reserves becoming economical, an almost unlimited energy source would become available. However, breeder reactor development has been slower and costlier than first estimated. In addition the concomitant chemical reprocessing facilities, are seen as presenting a serious risk of nuclear weapons proliferation. As such, the desirability of the breeder-reactor fuel cycle is now being seriously questioned. Other reactor types have near-breeding characteristics, such as the CANDU thorium cycle, and the gas-cooled reactor which also uses ^{233}U fuel. These reactors can stretch the fuel resource, but their fuel cycles have not been developed to the same extent as that of the liquid-metal cooled fast breeder reactor.

Accelerator breeding provides an alternative means of greatly extending the natural uranium fuel resource^{3,4}. It can produce the fissile fuel for present-day, well-developed light water reactors, whilst maintaining the high proliferation resistance of the present fuel cycle.

The background to accelerator breeding

The growth of accelerator technology can be attributed wholly to government funding for basic research in nuclear and elementary particle physics over the past 30 yr. Among the many types of accelerators developed, one in particular offers the potential to accelerate large beam currents (many mA)

Fig. 2 Measured yield of neutrons by bombardment of a heavy metal target with high energy protons. a, U, 10.2 cm diameter $\times$ 61 cm; b, Pb, 20.4 cm diameter $\times$ 61 cm; c, Pb, 10.2 cm diameter $\times$ 61 cm; d, Gn, 10.2 cm diameter $\times$ 61 cm; e, Be, 10.2 cm $\times$ 10.2 cm $\times$ 91.6 cm.

continuously to very high energies (thousands of MeV)—the linear accelerator^{5,6}. A linear accelerator added to the nuclear fuel cycle makes a different method of producing fissile material possible. This uses the neutrons produced by a nuclear reaction in the target struck by the high energy beam.

At very high energies, charged particles (in this case protons or deuterons generated by the accelerator) interact with the target material, mainly through nuclear inelastic collisions.

When the particle hits a complex nucleus, nucleons are ripped off, or spalled from the nucleus. The energy of the spallation products is sufficient to induce additional spallation in an intra- or inter-nuclear cascade^{7,8}. Ultimately, the energy of the incident particle not carried away by the escaping particles will be shared by the remaining nucleons of the target nuclei leaving the residual nuclei in a highly excited state. This is followed by a statistical evaporation process in which nucleons and γ rays are emitted until the nuclei are de-excited. Thus, neutron multiplication occurs in any target material. Heavy materials, however, will result in larger neutron yield. Additional neutron multiplication will occur in fissile materials due to the fast fission process⁹. Figure 1 shows the processes involved in a uranium or thorium target struck by a high energy proton. Figure 2 shows measured values of neutron multiplication for targets of different materials and given geometry at different proton energies¹⁰.

The earliest exploration into the use of accelerators to produce fissile materials was made by a group at Berkeley in the early 1950s. The device was called the MTA (materials testing accelerator¹¹). The objective was to produce plutonium for the weapons programme from the tails low in ^{235}U accumulating at the Oak Ridge diffusion plant. The feed to the separation plant at the time was mostly uranium from abroad, principally the Belgian Congo and South Africa. If the diffusion-plant tails could have been turned into plutonium, this would have freed the US from dependence on a foreign source of uranium. The project was abandoned when substantial uranium deposits were discovered in the western US. Construction of the accelerator had already begun when the MTA project was ended in 1954, and an accelerator prototype had operated successfully.

In 1952, Lewis, in Canada, had considered the idea for the production of power¹², and in the 1960s, the Canadian concept had evolved into the intense neutron generator (ING) which would have supplied an intense neutron source for research¹³. Although the project was not funded because of financial constraints the Canadians have continued development of the accelerator breeder and its use in the Canadian CANDU reactor fuel cycle¹⁴. Recently, interest has grown because of the success of new linear accelerator designs and the interest in alternative ways of producing nuclear power and nuclear fuels. This led to a 1977 symposium¹⁵ held at Brookhaven National Laboratory¹⁵, which coincided with increased concern over risks of proliferation of nuclear weapons.

Research status and system outline

Present interest in accelerator breeders is mainly concentrated in North America. A sustained programme has been continued for years at Chalk River, Canada. The Canadian team has worked on all aspects of the accelerator breeder as a producer of fissile ^{233}U from thorium to fuel CANDU reactors. Since the CANDU reactor burning ^{233}U , has near-breeding characteristics (conversion ratio ≥ 0.9) a single 0.3 A–1 GeV accelerator breeder could supply fuel for about 10 reactors. This fuel cycle does, however, require chemical reprocessing like that of the breeder reactor, but this fuel cycle also makes perhaps the most efficient use of the accelerator breeder.

The work carried out at Chalk River includes studies, development, and prototyping of new accelerator structures, detailed calculations and experimental validation of target neutronics, and system studies within the context of the Canadian nuclear power programme.

Los Alamos Scientific Laboratory plans to undertake a major experimental programme at the 800 MeV proton accelerator, LAMPF (linear accelerator meson physics facility) to study breeding, target neutron yield, and fissile material production rates. Oak Ridge and Argonne National Laboratories have had small feasibility study programmes dealing mostly with neutronics aspects, systems and economics.

Finally, Brookhaven National Laboratory has a programme to study feasibility of the accelerator breeder and its economic desirability within the context of US policy of a proliferation-resistant fuel cycle. There is also the intention to produce fuel for existing LWRs¹⁶. In this sense the approach is quite different from that taken by the Canadians. The Brookhaven study has yielded two highly proliferation-resistant nuclear fuel cycles showing promise in terms of technical feasibility and economic desirability.

Fig. 3 Linear accelerator fuel regenerator nuclear fuel cycle.

Figure 3 shows the linear accelerator fuel enricher regenerator (LAFER) fuel cycle. It is called an enricher regenerator because its main function is the topping up of the initial fuel enrichment before burning and to rejuvenate the burned or spent fuel elements discharged from the reactor to make possible a second burn cycle. Thus, fuel assemblies that presently are enriched to ~3% ²³⁵U and burned to 30,000 MWD tonne⁻¹ could yield 60,000 MWD tonne⁻¹ with an initial enrichment of only 2%. No reprocessing of fuel is involved. This scenario would require 1 LAFER for each 3 LWRs, the LAFER being a 0.3 A-1.5 GeV linear accelerator with a calculated annual production of 1.1 tonnes of fissile material in conventional LWR fuel assemblies.

In principle, one could consider irradiating fuel assemblies in the LAFER through more than two cycles, with correspondingly better fuel utilisation and better economics. However, uncertainties concerning the effects of fission product buildup, and of radiation and corrosion damage to materials indicate that we should not consider more than about 60,000 MWD tonne⁻¹ burn-up at present.

The natural uranium requirement to fuel an LWR operating in conjunction with a LAFER is calculated to be 1,750 tonnes over its 30-yr life. This is about 3 times less than the 6000 tonnes presently required. Also the rate of generation of spent fuel is only half that of the conventional fuel cycle.

Another proliferation-resistant, accelerator-breeder fuel cycle is shown in Fig. 4. Here, the accelerator re-enriches spent fuel discharged from an LWR back to the fissile concentration required for burning. The fuel assemblies are then dismantled and refabricated without separation of the fissile material component of the fuel. Thus, reprocessing in this case removes the high vapour pressure fission products only. No stream of highly enriched or pure fissile material is ever present. And as the fuel is dilute and radioactive at all times, there would be little or no risk of theft. The fuel is then burned again in the conventional LWR. This approach to the accelerator-breeder fuel cycle has obvious advantages. Like the breeder reactor, it increases the uranium resource availability whilst remaining within the well proved technology of existing light-water cooled

reactors. Here again, one accelerator breeder would be required to support three 1,000 MW(e) power reactors.

The laboratories involved in these studies seem to agree that the linear accelerator technology for this application is well in hand and that the major technical problems reside with the target system. These problems concern the ability to optimise neutron multiplication and capture (the fissile fuel production rate) in the presence of severe engineering constraints such as radiation damage to materials, power dissipation and so on. However, substantial progress has been achieved during the past year and accelerator breeders are not only possible but could be built and demonstrated at a reasonable cost and within a period of around 10 years.

Brookhaven facility

The most advanced facility design is that developed at Brookhaven National Laboratory. This facility would consist of two distinct parts: a 0.3 A-1.5 GeV linear accelerator, or linac, and its associated target-blanket assembly with power generation system.

The head-end of the linear accelerator would consist of an Alvarez drift-tube linac¹⁷, operating at a radio frequency of about 200 MHz up to an energy of 150 MeV. The Alvarez structure would be followed by a so-called $\pi/2$ mode disk-and-washer loaded waveguide structure, up to the final energy. This type of structure has been developed successfully in the USSR¹⁸. An acceleration rate of 1.5 MeV⁻¹ seems close to optimum. The 1.5 GeV linac is about 1000 m long. The design of the accelerator lies well within present capabilities and no fundamental

Fig. 4 Linear accelerator fuel producer nuclear fuel cycle (with reprocessing).

problems are anticipated. Experience with linear accelerators indicates that such machines can be operated without appreciable beam loss during acceleration, so that residual radiation will not handicap maintenance of the machine.

The distance between the target system and the accelerator is about 100 m. This drift length, containing isolation valves and instrumentation, will keep the accelerator free of any contamination by the high-radiation target area. Figure 5 shows the design of the target. It consists of a primary lead-bismuth target, stopping the entire proton beam, and of a secondary target (blanket) containing the fertile uranium material. The primary target consists of falling liquid lead-bismuth columns or jets arranged to provide an evenly distributed neutron source. This is accomplished by providing a variable target density with respect to target depth, and by stepping the target to intercept different parts of the proton beam at different points within the neutron source area. The liquid-bismuth jets operate in the

Fig. 5 Accelerator breeder target-blanket concept.

vacuum of the containment vessel, which is directly connected to the accelerator by the beam transport system. No window material is required between the accelerator and the target. The uranium fertile material in the blanket consists of LWR fuel assemblies located in individual pressure-tubes. These surround the primary target neutron source in a manner consistent with minimisation of neutron leakage, parasitic absorption and mechanical design constraints. The assemblies of fuel, coolant and moderator are designed to remain highly subcritical in any circumstance. During an irradiation cycle, fuel shuffling is required to achieve good control of reactivity buildup. The neutron multiplication due to fast fission in the blanket produces thermal energy. This energy, as well as that generated by the proton beam in the lead-bismuth target, is used to generate electrical power by a conventional steam-turbine system. The safety considerations applicable to the target-blanket system are the same as those for an LWR, with the notable exception that the target of the accelerator-breeder is subcritical. However, the entire target-blanket and primary coolant systems are in a containment building similar to that of a conventional power reactor with the same safety features.

Economics and future prospects

Economic analyses carried out at Brookhaven and elsewhere indicate that the cost of fuel produced by an accelerator breeder is high, between \$200 and \$300 per gramme of net fissile fuel produced. This compares with the present cost of $< \$100 \text{ g}^{-1}$ of net ^{235}U burned in LWRs.

A better indication of the accelerator breeder economic prospects is obtained by looking at the entire nuclear fuel cycle cost, or rather, the cost of electric power to the consumer. On that basis, the consumer power cost was calculated using the accelerator breeder in conjunction with LWRs as shown in Figs 3 and 4. It was found that the cost per kWh would increase by

about 25%. At present, therefore, the accelerator breeder cannot compete on a strict economic short-term basis with the other means available to produce the fuel required for power reactors, namely the mining and enrichment of natural uranium. But will things change in the future?

The projected scarcity of uranium had led to the development of the breeder, and the cost of electricity produced by the breeder fuel cycle will be higher than what we are now paying (notwithstanding inflation). The accelerator-breeder-LWR fuel cycle cost may be competitive with the reactor breeder fuel cycle cost. There are also other cost parameters more difficult to assess. For example, what are the cost benefits of the continuing exploitation of the same, and well developed, LWR technology, of the inherent proliferation resistance of the fuel cycle using the accelerator breeder, of the environmental impact of decreased mining activity (especially as we move to lower yield ore bodies) and of the ability to use spent fuel now being stored indefinitely in storage pools?

Also, projections of nuclear fuel cycle cost are clouded with many uncertainties such as: projected cost of U_3O_8 , new licensing requirements for plant safety, spent fuel storage and waste disposal, safety problems specific to the breeder reactor, cost and social desirability of the nuclear fuel cycle of the future, and so on.

The economic picture painted here is one of confusion. It points out the many difficulties at arriving at an objective cost-benefit analysis and projecting the potential of the accelerator breeder in the nuclear fuel cycle, or of any other competing system as well¹⁹. We can conclude however, that accelerator breeding offers a real alternative to the breeder reactor. It does so while retaining the present safety of the existing LWR based nuclear fuel cycle. Accelerator breeders are an extension of existing technologies, and hence can be developed at a reasonable cost and could be used commercially within the next 20 years.

IUE observations of absorption by hot gas in the nebula NGC6888

M. C. E. Huber & H. Nussbaumer

Atomic Physics and Astrophysics Group, ETH-Zentrum, Zurich, Switzerland

L. J. Smith, A. J. Willis & R. Wilson

Department of Physics and Astronomy, University College London, Gower Street, London WC1, UK

New UV observations of Wolf-Rayet stars obtained with the IUE satellite show narrow absorption components in the highly ionised species of SiIV and CIV. In the case of the WN6 star HD192163 each resonance transition in the above ions exhibits two components, one undisplaced in wavelength and one blueshifted. The latter components are shown to arise in the nebula NGC6888 surrounding HD192163, and these are the first observations of absorption lines arising in a nebula associated with an early-type star. The strengths of the 'interstellar' SiIV and CIV lines in four WR stars and two other early-type stars are compared. There seems to be no correlation in the strengths of these lines with either stellar distance or colour excess, suggesting that they arise not in the general interstellar medium but in material more intimately linked with the stars themselves.

ULTRAVIOLET observations by the Copernicus satellite of several early-type stars revealed sharp absorption lines in the resonance lines of highly ionised species of SiIV, NV and OVI (ref. 1). These lines have usually been attributed to the presence of a hot, low density coronal gas in the interstellar medium resulting from successive supernovae explosions and occupying much of interstellar space². Recent IUE observations of the X-ray binary source HD153919 (ref. 3) have shown the presence of sharp absorptions in SiIV and CIV, whose strengths are more consistent with the presence of an extensive region of photoionised gas associated with the X-ray source.

This article presents further observations of sharp 'interstellar' lines arising in highly ionised species. These are seen in the spectra of several WR stars which are being studied as part of an extensive investigation of this stellar class using the IUE satellite. The sharp absorptions in the SiIV, CIV and AlIII resonance lines of the star HD192163 are split into two

components, one undisplaced in wavelength and one blueshifted. The blueshifted components arise in the nebula NGC6888 surrounding the star, representing the first unambiguous observations of absorption lines in a nebula associated with a hot early-type star. The strengths of the observed sharp SiIV and CIV absorptions in four WR stars and two other early-type stars are compared. We conclude that there is no correlation between the strengths of these lines and either distance or colour excess, which suggests that their origin is not in the general interstellar medium but in material more intimately linked with the stars themselves.

Observations

The IUE satellite has been described by Boggess *et al.*^{4,5}. The present observations of four WR stars were obtained in the high resolution mode ($\delta\lambda \sim 0.1-0.2$ Å) and cover the full available wavelength from 1,150 to 3,200 Å. Details of the observations and some information about the stars are given in Table 1. The

spectral types and V -magnitudes are taken from ref. 6; the colour excesses $E(B - V)$ from ref. 7 and the distances, d , from these data and the absolute magnitudes given in ref. 8.

Table 2 Equivalent widths, W_λ , velocity shifts, v , and column densities for the displaced SiIV, CIV and AlIII absorption lines observed in the UV spectrum of HD192163

Line	SWP 2517			SWP 1668		
	v (km s ⁻¹)	W_λ (Å)	log N	v (km s ⁻¹)	W_λ (Å)	Log N (cm ⁻²)
SiIV 1,393.7	86	0.21	13.36	97	0.17	13.27
SiIV 1,402.8	86	0.14	13.49	96	0.15	13.52
CIV 1,548.2	82	0.20	13.69	97	0.17	13.61
CIV 1,550.8	68	0.12	13.76	92	0.10	13.68
AlIII 1,854.7	93	0.15	12.96	97	0.12	12.86
AlIII 1,862.8	85	0.07	12.93	97	0.10	13.08

The raw data were reduced by the ESA observatory in Madrid and include corrections for relative intensities, background and echelle grating-blaze effects. The wavelength scales were determined by assigning the vacuum laboratory wavelengths to the narrow interstellar lines arising in low ionisation species (such as CII, 1,334.4 Å, 1,335.7 Å, OI 1,302.2 Å).

Sections of the two spectra of HD192163 covering the lines of SiIV 1,393.7 Å, 1,402.8 Å, CIV 1,548.2 Å, 1,550.8 Å and AlIII 1,854.7 Å, 1,862.8 Å are shown in Figs 1, 2 and 3 respectively. As well as the sharp components to these lines the SiIV and CIV lines are seen as broad P-Cygni profiles formed in the extended expanding atmosphere of the WR star. Each transition displays two sharp components; one, undisplaced at the rest frame of the other interstellar lines, and one, blueshifted. The velocities of the shifted components are given in Table 2 and are seen to be very similar, implying a common origin. The mean value is 90 ± 9 (r.m.s.) km s⁻¹.

Fig. 2 The IUE spectra of HD192163 in the region of the CIV 1,548.2 Å, 1,550.8 Å doublet. The two components to each CIV line are marked. R marks the position of a camera resseau. a, SWP 1668; b, SWP 2517.

HD192163 is embedded in the nebula NGC6888, which is one of the ring nebula surrounding certain WN stars. Interferometric observations of this nebula in the visible H α , H β , and [NII] lines by Lozinskaya⁹ and Georgin and Monnet¹⁰ have demonstrated that the nebula is expanding from the central WR star with expansion velocities in the range 55–110 km s⁻¹. The infrared mean expansion velocity for NGC6888 is thus very similar to the observed velocity shifts of the sharp SiIV, CIV and AlIII displaced lines, demonstrating that these absorption components arise in NGC6888.

The NV 1,238.8 Å, 1,242.8 Å lines, however, are not seen in either displaced or undisplaced absorptions superimposed on the broad P-Cygni profiles of this doublet seen in the spectrum of HD192163. Their absence is discussed below. The 2,795.5 Å, 2,802.7 Å lines of the ion MgII are observed but are heavily saturated and broadened through normal interstellar absorption, thus masking any nebula component. Indeed the distance and reddening of HD192163 ensures that most of the other interstellar lines observed from common species are saturated, again masking any nebula components.

The measured equivalent widths and column densities for the nebula absorption components to the SiIV, CIV and AlIII doublets are given in Table 2; f -values for these transitions are from ref. 11. The column densities have been determined by assuming that these lines lie on the linear part of the curve of growth, an assumption confirmed by the fact that the doublet ratios for each ion are approximately in their expected ratio of 2:1. The strengths of the undisplaced components to these lines together with those observed in the spectra of other stars are given in Table 3.

Discussion

The electron density, N_e , and electron temperature, T_e , in the region of NGC6888 which gives rise to the observed optical emission have been determined as 400 cm⁻³ (ref. 12) and 19,000 K (ref. 9) respectively. The thickness of the nebula shell giving rise to the optical and radio emission has been determined as 0.01 pc (ref. 13). If it is assumed that the observed SiIV and CIV absorption arises in this region, the corresponding mean number densities of these species would be: $n(\text{CIV}) \sim 1.6 \times 10^{-3}$ cm⁻³ and $n(\text{SiIV}) \sim 8.3 \times 10^{-4}$ cm⁻³. Assuming that hydrogen is fully ionised in the nebula shell, $n(\text{H}) = N_e$, these numbers imply $n(\text{CIV})/n(\text{H}) \sim 4 \times 10^{-6}$ and $n(\text{SiIV})/n(\text{H}) \sim 2 \times 10^{-6}$. The further assumption of a normal cosmic abundance distribution in the nebula ($n(\text{C})/n(\text{H}) = 3.3 \times 10^{-4}$ and $n(\text{Si})/n(\text{H}) = 3.3 \times 10^{-5}$) would imply $n(\text{CIV})/n(\text{C}) \sim 10^{-2}$ and $n(\text{SiIV})/n(\text{Si}) \sim 0.06$. These values are completely at variance with the expected ionisation ratios for this region of the nebula. The ionisation balance calculations of Thuan¹⁴ for HII regions around OB stars indicate that with the effective temperature of the central WN6 star of 30,000 K (refs 7, 15) photoionisation is negligible for producing CIV and SiIV in the nebula, although this process could become significant if the stellar temperature were higher than 35,000 K. With $T_e = 19,000$ K and the ionisation balance calculations of Jordan¹⁶, Nussbaumer and Storey¹⁷ and Landini and Fossi¹⁸ the expected CIV/C and SiIV/Si ratios are both $\ll 10^{-4}$. Only by increasing the abundances of carbon and silicon in the nebula by over two orders of magnitude could the expected ionisation be accommodated by the observed SiIV and CIV column densities and the hydrogen density. Bearing in mind that the central star is a WN rather than a WC, this seems to rule out the optical and radio nebula region as the source of the SiIV and CIV absorption.

Johnson and Hogg¹³ have suggested that the nebula NGC6888 is formed by the sweeping up of the local interstellar material by the stellar wind of the central WR star, a hypothesis supported by Avedisova¹⁹ who showed that the mass of the nebula is consistent in this model with an original interstellar density of 1–2 atom cm⁻³. However, Wendker *et al.*²⁰ suggest that a substantial fraction of the nebula mass comes from the material shed by the WR progenitor during its evolution to the WR phase, a view supported by the recent evolutionary scenario

of Conti²¹ and Willis and Wilson⁷ linking the Of and WR stars, and the very high mass loss rates ($\sim 10^{-4} M_{\odot} \text{ yr}^{-1}$) that are now believed to be appropriate for the WR stars^{21,23}. In either case, as the velocities involved are large, considerable shock heating on the inner boundary of the nebula can be expected, with temperatures in this region perhaps lying in the range $3-6 \times 10^5$ K according to the model of Avedisova¹⁹. Therefore, the observed absorptions in the highly ionised SirV and CrV species are probably formed in this hot region of the nebula. Note that

from the observed column densities of SirV, CrV and AlIII and the ionisation balance calculations of Jordan¹⁶, Nussbaumer and Storey¹⁷ and Landini and Fossi¹⁸ for a low density plasma the infrared ionisation temperature is $\sim 60,000 \pm 8,000$ K, somewhat lower than predicted in the model of Avedisova¹⁹. If this temperature were correct, the expected NV/CrV ratio is $\sim 10^{-4}$ and thus the NV resonance line nebula absorptions would be expected to be negligible, in agreement with the present observations.

A comparison of the strengths of the undisplaced absorption components of AlIII, SirV and CrV seen in the spectra of HD192163 with those observed in the three other WR stars listed in Table 1; in the OfV star ζ Oph^{24,25} and the X-ray binary source HD153919 (ref. 3) is given in Table 3. Also included in Table 3 are the measured strengths of the interstellar lines of the resonance lines of several common ions observed in these stars, the colour excesses $E(B-V)$ and the distances to these stars. The strengths of the low ionisation interstellar lines in HD192163 and ζ Oph are in the ratio $3(\pm 0.4):1$, which is broadly in line with the colour excess ratio of 2:1 bearing in mind the saturation effects which are present in most of these lines. However, the corresponding ratio for the high ionisation SirV and CrV lines is ~ 20 , completely at variance with the colour excess and low ionisation gas column ratio. The corresponding ratio of the strengths of the SirV and CrV lines in HD192163 and HD153919 is $\sim 3:1$, although in this case both the colour excesses and distances are very similar. There thus seems to be little correlation between the strengths of these sharp 'interstellar' lines of SirV and CrV with either distance or colour excess.

Furthermore, a comparison of the strengths of these absorptions in the four WR stars currently observed in our IUE programme, confirms this assertion of a lack of a correlation with either distance or colour excess. Such a comparison for the CrV 1,548.2 Å, 1,550.8 Å doublet observed in the four WR stars listed in Table 1 is shown in Fig. 4. The most distant star, HD165763, exhibits the weakest CrV absorptions, whilst the least reddened star, HD50896, shows these lines with strengths comparable to those observed in HD192163. Although largely saturated the low ionisation interstellar lines listed in Table 3 have strengths in the four WR stars which are broadly in line with the relative stellar distances and colour excesses.

Conclusion

In the present sample of stars there seems to be no correlation between the strengths of sharp interstellar absorptions in the

Fig. 3 The IUE spectra of HD192163 in the region of the AlIII 1,854.7 Å, 1,862.8 Å doublet. The two components to each AlIII line are marked. R marks the position of a camera readout and S that of a noise spike in the data. a, SWP 1668; b, SWP 2517.

Fig. 4 The IUE spectra of the four WR stars: a, HD156385 (WC7); b, HD165763 (WC5); c, HD192163 (WN6); and d, HD50896 (WN5) in the region of the Crv 1,548.2 Å, 1,550.8 Å doublet. The sharp Crv interstellar components in each star are marked and, in the case of HD192163 the components that arise in the nebula NGC6888.

highly ionised species of SiIV and CIV with distance or colour excess which suggests that these features are not formed in the hot coronal gas permeating interstellar space. It seems more likely that their formation is a local effect closely linked to the WR stars themselves. A 'local' conclusion was also reached by Dupree *et al.*³ to explain the strengths of the highly ionised interstellar lines observed in the X-ray binary HD153919. They argue that the species are produced by photoionisation in the

radiation field of the X-ray source. In the present case it seems more profitable to consider the effects of the interaction of matter ejected by the WR stars and their progenitors with the interstellar medium.

Although there is no correlation between the strengths of the highly ionised interstellar lines in the four WR stars with other interstellar parameters, it is striking that they are much stronger in the two WN stars than in the two WC stars. The sample is too small to establish this as a real effect but the result may be linked to the different physical and chemical characteristics of the two WR sequences or their evolutionary state. Further observations of a larger sample of WR stars are clearly needed to establish this.

In the case of the WN6 star HD192163, it was shown above that absorption components in the SiIV, Crv and AlIII resonance lines also arise in the nebula NGC6888 surrounding the star. More detailed modelling of these lines together with observations of the corresponding nebula emissions in these and other species, should enable the properties of that nebula to be accurately determined, a topic under investigation.

Finally HD192163 has been observed to have a pronounced excess strength in its 2,200 Å band which is believed²⁶ to arise in NGC6888. It may be pertinent to consider whether the great strength of the 2,200 Å band and of the CIV interstellar lines reported here (the strongest yet observed) are in some way linked.

Short-range structure for amorphous intertransition metal alloys

Rong Wang

Pacific Northwest Laboratory, Richland, Washington 99352

Amorphous intertransition metal alloys may be a special class of the glassy state whose short-range structure is random tetrahedral close packing of soft atoms similar to those in the crystalline counterparts. A short-range structure is described based on random stacking of Kasper polyhedra and atomic disorder at the stacking misfit, and has tetrahedral sites, high atomic coordination numbers and asymmetric shapes of atoms.

A STRUCTURAL concept is introduced here for the amorphous intertransition metal alloys by alloying an early transition metal, T_1 , with a late transition metal, T_2 . These are shown in groups in Table 1. Recent investigation of formation, stability and properties of refractory amorphous alloys of W-Fe (ref. 1), Mo-Co (ref. 2), and Mo-Ni (ref. 3) at crystalline μ -phase or δ -phase compositions indicates that these amorphous alloys may have a crystal-like, short-range structure that deviates from the dense random packing of hard spheres (DRPHS)⁴⁻⁶. Consequently, it has been suggested that the amorphous structure of a $\text{Mo}_{46}\text{Co}_{54}$ alloy is a random tetrahedral close packing of atoms resembling

Table 1 A division of transition metals of the Periodic Table

the random interpenetration of Kasper polyhedra in three-dimensional space². This short-range structure for the intertransitional metal alloys is conceived from the concepts of Wang and Merz^{7,8} and Goodman⁹ that mixed atomic bondings of the crystalline counterparts are retained in the amorphous solids and contribute to their thermal stability. We present here evidence and structural features supporting the argument that short-range structure in this type of metallic glass should closely resemble that found in compositionally related crystalline phases.

Evidence for crystal-like short-range structure

Amorphous intertransition metal alloys probably have a crystal-like, short-range structure because of the following unique aspects of formation, structure and properties, which are closely related to those of the intermetallic compounds.

(1) Formation of the amorphous intertransition metal alloys is favoured by compositions that are at, or near, a eutectic point or a complex-structured intermetallic compound. Formation by quenching from the liquid state clearly benefits from an under-cooled liquid with composition near the eutectic point, while at high cooling rates (that is by vapour deposition) formation occurs at compositions of the intermetallic composition^{1-3,10}.

(2) Amorphous intertransition metal alloys generally show a sharp first diffraction peak that corresponds to a coherent diffracting domain size between 13 and 18 Å, depending on the method of preparation, composition and cooling rate^{1,2,11,12}. The sharp diffraction peak indicates a high degree of short-range order which was once considered as evidence of microcrystallinity for liquid-quenched Nb-Ni and Ta-Ni alloys¹². The calculated scattering intensities based on relaxed DRPHS models only qualitatively explain the details of the observed intensities for amorphous Cu-Zr alloys¹³⁻¹⁵. The discrepancy between the observed and calculated scattering intensities also was found in amorphous Nb₃Ge and Nb₃Si¹⁶, due to the asymmetrical nearest-neighbour maximum found in measured dis-

Fig. 1 The four triangulated coordination polyhedra with 5- and 6-fold vertices observed in the intertransition metal compounds (from ref. 27).

Fig. 2 Two-dimensional analogue of Kasper polyhedra to show irregular triangles that will be irregular tetrahedra in three-dimensional space (from ref. 26).

tribution functions for amorphous Nb₃Ge. Thus, local order in amorphous Cu-Zr has been considered as being related to the crystallised phases¹⁷.

(3) The densities, or packing factors, calculated from the DRPHS models were between 10 and 30% smaller than those observed for the amorphous alloys, depending on the relaxation processes^{16,18,19}. The measured densities of the amorphous intertransition metal alloys are closer to the values of the corresponding crystalline intermetallic compounds^{1,2}.

(4) High thermal stability is usually associated with the amorphous intertransition metal alloys¹⁰, that is, the crystallisation temperatures of Nb₄₀Ni₆₀, Mo₅₀Ni₅₀, and Zr₅₀Cu₅₀ are above 600 °C and those of W₅₀Fe₅₀, and Mo₄₆Co₅₄ alloys are above 800 °C^{1,2}. Several amorphous films of Ta-Re, Mo-Re and Mo-Ru²⁰ at the compositions near the crystalline intermetallic compounds also exhibit similar high thermal stabilities. On the other hand, thin films of single transition metals, such as Zr, Hf, Ta, Mo, Cr, W, and Re, are either microcrystalline or amorphous but stable only below room temperature^{20,21}.

(5) High microhardnesses ranging from 800 to 1,100 kg mm⁻² are typical for the amorphous intertransition metal alloys, even though the differences in electronegativity between the two alloying elements are small. The microhardnesses are comparable to those of the crystalline intermetallic compounds and indicate strong covalent bondings involving d electrons; these bondings also resemble those of the crystalline phases.

These properties suggest that amorphous intertransition metal alloys belong to a special class of glassy state that involves strong atomic interactions among d electrons—similar to those in the intermetallic compounds. Thus, the short-range structure is expected to incline more towards the short-range order of the crystalline phase and to deviate from the random close packing of hard sphere models as far as the metallic glasses and the simple liquids are concerned.

Fig. 3 Proposed structure for amorphous intertransition metal alloys as made by random stacking of irregular tetrahedra shown in a two-dimensional analogue.

Short-range structure

The short-range structure of the amorphous intertransition metal alloys is proposed to be random tetrahedral close packing of soft atoms. This structure is derived from the crystal chemistry of the intertransition metal compounds: the crystal structures are primarily based on tetrahedral close packing of atoms²²⁻²⁵. One can achieve packing with a single type of tetrahedral interstices only by irregularly shaped tetrahedra. Intensive analyses of the known structures of intertransition metal compounds have revealed that there are only four triangulated coordination polyhedra (the so-called Kasper polyhedra²²) that have 5- and 6-fold vertices as shown in Fig. 1. In many crystal structures, these polyhedra interpenetrate in such a way that every vertex atom becomes the centre of a polyhedron. Figure 2 shows the meshing of polyhedra (the 5-fold vertices, for instance). It is taken from Laves' analog²⁶ and is viewed in two-dimensional space. In this structural analogue, the T_1 atom has a CN 7 (seven neighbours close to each T_1 atom), and the T_2

atom has a CN 5 (five neighbours close to each T_2 atom). Crystal structures based on the stacking of these Kasper polyhedra for intermetallic compounds are discussed in detail by Kasper²², Shoemaker *et al.*^{24,25} and Bergman *et al.*²⁷.

Consequently, the proposed short-range structures of the amorphous intertransition metal alloys will also contain interpenetrated Kasper polyhedra similar to those occurring in the intermetallic compounds. The short-range structure of amorphous alloys may be constructed by random stacking of all four types of the Kasper polyhedra, and by introducing atomic disorder at the stacking misfit. A two-dimensional analogue can be used to show the structure of amorphous alloys (Fig. 3) and to compare it with that of the crystalline form (Fig. 2).

The amorphous structure was composed of two sets of stacking configurations based on the 5-fold vertices—the stacking configuration for the crystalline structure (Fig. 4) and the additional stackings uncommon to the crystalline structure (Fig. 5).

Due to long-range order, the stacking configurations for the crystalline structure are limited by three ways able to connect two vertices and one way able to stack four vertices (Fig. 4). However, the amorphous structure contains additional random stackings, as in Fig. 5, which shows both perfect matching of the vertices side by side and the stacking misfit where stacking cannot be matched at one atomic site.

Stacking misfit causes atomic disorder, that is ambiguity of atomic identity at the corner of the 5-fold vertex. For example, the atomic disorder at site 1 occurs because both T_1 and T_2 atoms should occupy this site if the edges of the vertex are made of four T_1 and one T_2 atom. This atomic disorder is common when more than two vertices are stacked randomly. The atomic disorder at site 2 is caused by stacking of three vertices in a specific configuration so that T_1 atoms form a triangle in which one side (connected by dash line) is too short for the normal T_1 - T_1 distance. Either this compresses the T_1 atoms, or one of the T_1 atoms will be replaced by a T_2 atom. In fact, these stacking misfits are also observed in intermetallic compounds at atomic coordination points 13 and 14 (ref. 28).

In constructing the amorphous structure analogue, many 5-fold vertices need to be distorted slightly from ideal shapes in the crystalline structure to lower the stacking misfits in the amorphous structural framework. These distortions were made by hand-adjusting the atomic positions in the vertices after the framework was completed. The atomic position adjustments would not usually exceed 10% of its interatomic distances. The distortion causes the final amorphous structure analogue, shown in Fig. 3, to contain a range of interatomic distances as shown in Fig. 6. As far as short-range atomic interaction is concerned, the two-dimensional amorphous structure analogue is similar to that of the crystalline structure, except a small portion of T_1 and T_2 atoms have the intermediate CN 6.

Discussion of the short-range structure

The structure described here is truly amorphous and contains continuous, random packing of atoms. It should not be considered as a microcrystalline model because there are no apparent line or surface discontinuities such as grain boundaries, and there is no periodicity in any direction. However, short-range atomic interactions, similar to those of crystalline compounds, are retained by stacking various types of polyhedra and atomic disorders at random. The types of polyhedra and the stacking configuration that dominate the amorphous structure would vary according to the composition, alloy system and cooling rate; primarily, however, they would be those of the nearby crystalline compounds, such as the μ -phase polyhedra²⁸ for amorphous $W_{50}Fe_{50}$, $Mo_{46}Co_{54}$, and $Nb_{50}Ni_{50}$.

Several features related to atomic size, coordination number and atomic interactions can be expected for the real amorphous intertransition metal alloys. The atomic size in these amorphous structures will be less specific because the atoms will assume more asymmetric shapes as the atomic coordination number increases from 12 to 16 (those observed in the intermetallic compounds). Consequently, high packing density and atomic

Fig. 4 Stacking configurations of the 5-fold vertices in both crystalline and amorphous structure analogues: a, a single 5-fold vertex; b, connections of two vertices; and c, stacking of four vertices.

interactions among unlike atoms are expected. These can be viewed from the two-dimensional structure analogue of Fig. 3 which consists of 29 T_1 atoms, 25 T_2 atoms and four disordered atoms. A packing density similar to that of the crystalline analogue is expected because T_1 atoms have CN 7 and CN 6, but T_2 atoms have CN 5 and CN 6, and small percentage (7%) of the disordered atoms. The occurrence of different atomic interactions (Fig. 6) shows that with a nearly 1:1 ratio of T_1 and T_2 atoms, there are almost twice as many T_1 - T_2 interactions than T_1 - T_1 interactions, and the T_2 - T_2 interactions are less significant. Diffraction studies have indicated that such strong atomic interactions occur among the unlike atoms for the real amorphous structures, such as Cu-Zr¹⁵, Nb₃Ge¹⁶, and RE-Tm^{18,19}.

Relationship to the formation and thermal stability

The formation and thermal stability of the short-range structure that contains a mixture of all four types of Kasper polyhedra can be understood as follows. The polyhedra represent possible low-energy configurations for atoms to be bonded in the solid, in positions that are separated by small energy differences. During quenching from the liquid or vapour state, the availability of four types of polyhedra allows several alternatives, or saddle-point energies, for atoms to be bonded to their neighbouring atoms in a way that prevents long-range atomic rearrangement. The total energy will not be significantly influenced by those small energy differences as long as the atoms are locally satisfying the requirement for strong d-d electron interactions. This explains the formation and stability of the amorphous inter-transition metal alloys.

For this type of amorphous structure, resembling a short-range ordered version of the crystalline phases, those factors governing the stability of the intermetallic compounds, such as the electron-to-atom ratio (e/a), the electronegativity, and the atomic size difference, would also be important for the forma-

tion and the stability of the amorphous structure¹⁰. In this regard, the short-range structure will apply to all the amorphous intertransition metal alloys whose crystalline counterparts follow the crystal chemistry principles as electron compounds. It is expected that binary and ternary amorphous alloys will be formed in the composition ranges in which intermediate phases such as σ , μ , δ , P and R phases are present. The above formation criteria and short-range structures can probably be extended to the other amorphous alloys based on Cr_3Si (A15), Laves (C14, C15, and C36) and $CaCu_2$ (D2_d) type phases that are related to the σ phase.

Evidence of a new isotopic anomaly from titanium isotopic ratios in meteoric materials

H. R. Heydegger*†‡, J. J. Foster* & W. Compston*

Titanium isotopic ratios in some terrestrial and meteoritic materials have been measured. Most have the same ratios within the experimental precisions. Some inclusion materials from the Allende meteorite have a statistically significant enhancement of the order of 1% in the 50/49 ratio, probably due to a nucleogenic anomaly in ⁵⁰Ti abundance.

SIGNIFICANT variations in the isotopic ratios of certain elements in some meteorites have been well established^{1–11}. Recent results^{10–13} show that some meteoritic materials may be simultaneously 'anomalous' in several elements. Numerous mechanisms^{14–18} have been proposed to explain these observations, and a common engendering phenomenon will probably be found for most, if not all, of the anomalies. To make a correct hypothesis, however, we need to establish the nature and magnitude of the anomalies in a large variety of elements.

A study of the isotopic composition of titanium in terrestrial and meteoritic materials, and especially inclusions in the carbonaceous chondrite Allende, has been undertaken, and some general results are reported here.

Titanium was studied because: (1) the titanium isotopic abundances observed in most materials are thought to be due to a combination of nucleosynthetic mechanisms¹⁹. Therefore it seems unlikely that the same pattern would arise from the phenomenon(a) which caused the anomalies in other elements; (2) most isotopic anomalies have been reported from refractory phases, and titanium is a refractory element in the classical condensation sequence²⁰; (3) carbonaceous chondrites are thought to have undergone less chemical and physical processing since their original formation, and inclusions in Allende have been the prime source of anomaly-bearing materials; (4) although no evidence of titanium isotope anomalies has been presented previously, uncertainties on the only reported study²¹ of similar materials were at a level sufficiently high ($\sim \pm 0.3\%$) for many anomalies observed in other elements to have been obscured.

Experimental techniques

Samples were chemically processed using standard dissolution and cation exchange methods^{22,23}. Blanks ran about 50 ng TiO₂. Samples containing about 50 μ g titanium were loaded onto triple rhenium filaments as aqueous or HF slurries, and were run on a mass spectrometer as described elsewhere²⁴. High side-

filament currents (about 3 A) were required to obtain sufficiently large ion currents ($\sim 10^{-13}$ A) for the less abundant isotopes. All data were taken using Ti⁺ beams, alternating between 47/49 and A/49, where A was 46, 48, or 50. A 'group' consisted of at least four 12 ratio sets for 47/49 and one set each for 46/49, 48/49, and 50/49, a minimum of six groups being obtained in the measurement of most samples. The amplifier zero level was measured at mass 52.5 twice during each group.

For all samples, the observed isotope ratios were found to change with time in a manner consistent with the Rayleigh single stage mass fractionation model, and to an extent comparable with that displayed by other refractory elements (such as Mg) (ref. 13).

To facilitate comparisons, all observed ratios were normalised to the value 1.3360 for 47/49, which is the weighted mean of the observed values obtained for the terrestrial materials and is assumed to be accurate to within $\pm 1\%$ of the true value. The ratio 47/49 was chosen as the basis for normalisation because there are no stable nuclidic isobars at these mass numbers, as there are for the other Ti isotopes. Observed ratios were automatically corrected for contamination from non-Ti nuclidic isobar ions as follows: masses 46 and 48 for Ca using mass 40; mass 50 for V using mass 51 and for Cr using mass 52. Data were not accepted if the isobaric contamination exceeded 0.1%. The entire mass spectrum between 38 and 56 was routinely recorded before the first group and after the last group for a given sample; a record between masses 45 and 53 was taken between groups. No data were accepted if base line irregularity greater than normal electronic noise levels between titanium mass numbers or unusual peak shapes were observed. In a few cases, it was necessary to correct for zero level drift (assumed to be linear with time) during a set. A few ($\sim 2\%$, mostly 48/49, which is more sensitive to transient baseline changes) outlying ratios and set means were rejected by Chauvenet's criterion in computing the means. In Tables 1–4, the uncertainties quoted are three times the sigma of the mean estimated from the observed dispersions of individual results. The three sigma level is preferable here to the more common two sigma level because, on average, one of every 20 replicate means at the latter level, but only one of every 250 replicate means at the former level, will be further from the grand mean than the quoted uncertainty.

Terrestrial materials

Titanium was isolated from the terrestrial materials listed in Table 1. More than 1,000 individual ratio measurements were made for each A/49 on samples prepared from these terrestrial

materials. Normalised results for measurements made in the period during which those on the meteoritic materials were also made are presented in Table 1 for both weighted (by inverse variance) and unweighted means, along with the three sigma of the mean uncertainty estimates. No significant differences were found between these recent means and those based on a comparable number of earlier measurements of the same (and other terrestrial) materials.

Because no significant differences among the various terrestrial materials are evident within the precision of the current measurements, all of this terrestrial titanium was assumed to be identical in its isotopic composition regardless of source, and the results were combined through weighted individual sample (six set) means, with results presented in Table 2 as terrestrial. The typical relative uncertainty of the means ($3\sigma_x/\bar{x} \sim 0.03\%$) is comparable to that reported recently by other laboratories for isotopic ratios of other elements in similar materials^{10,13}. Our values agree with most of the reported isotopic analyses of titanium well within the estimated $\pm 1\%$ accuracy. Therefore, our method apparently gives reasonable accuracy and precision for terrestrial materials.

Meteoritic materials

Allende whole rock powder: several samples were prepared directly from Allende powder (TiO₂ content 0.15%) obtained from the US National Museum (3529, S19, P20). The combined (weighted) normalised individual sample mean results of these measurements are given in Table 2.

The Allende whole rock powder titanium isotopic ratio results are not distinguishable from those for terrestrial materials within the experimental precision, which is comparable to that obtained for terrestrial materials. Therefore, our analytical methods seem to apply to Allende as well as to terrestrial materials.

Allende whole rock powder chemical leach fractions: Anders *et al.*^{25,26} have reported that most of the anomalous rare gases are associated with a small amount of the material in Allende, which they concentrated through a sequence of chemical leaches of Allende powder. From its chemical properties, they deduced this carrier to be a sulphide-rich phase. It has been proposed²⁷ that such a phase might be rich in ⁴⁶Ti sulphide derived from a condensing supernova shell. Therefore, a sequence of leaches similar (see Table 2 for details) to that used for the rare gas work^{25,26} was performed on two separate (~ 0.5 g) samples of the Allende powder described above. The titanium isotopic ratios of these various separate acid leach (two HCl, one HF, two HNO₃) samples were found to be the same within experimental precision, and all results were, therefore, combined (as six set means) to produce the values in Table 2. The overall relative precision is again roughly comparable with that observed for terrestrial materials. Included in these means are data from three samples which had been chemically reprocessed for titanium after the usual chemical treatment. The data for the reprocessed samples seemed to disperse in the same manner about common means as those for the one chemical cycle samples.

Table 2 Mean results for terrestrial and Allende materials

Material*	Normalised† Ti isotope ratios $\pm 3\sigma(\bar{x})\ddagger$			Mean no. of measured ratios included
	46/49	48/49	50/49

* See Table 1 and text for description of materials.

† See Table 1 for details.

‡ Separate contacts with concentrated HCl, HF, and HNO₃, each for ~ 12 h at about 80°C. Cycle performed twice with each Allende whole rock powder sample, with like fractions from both cycles combined and treated for Ti in usual manner. Acid leaches represents the combined data from two HCl, one HF, and two HNO₃ soluble fractions. Residue represents Ti isolated in the usual manner from the insoluble residue of the above acid leaches.

Allende inclusions: the largest oxygen and magnesium anomalies have been found in inclusions in Allende. Therefore, titanium from a variety of Allende inclusions has also been measured in this work. Most of these samples have been well documented mineralogically and chemically²⁸. We obtained aliquots of powdered whole inclusions which had not been (and were not) further separated before chemical processing. The samples varied between about 0.5 and 2.5% in TiO₂ content and represented all classes of inclusions listed by Taylor and Mason²⁸. These materials were processed using the same chemical procedures as for the terrestrial and whole rock materials described above; however, in some cases, the order of the ion-exchange steps was changed. Due to the small amounts of material available, replicate samples of all materials could not be processed; however, in those cases where replication was possible, agreement was found to be consistent within the precision of the individual measurements involved. The frequency distributions for the measured isotopic ratios of terrestrial and of inclusion material overlap sufficiently that, in the absence of several replicate determinations, none of the individual inclusions can be convincingly demonstrated to be different from terrestrial material in titanium isotopic composition. However, as the results for the various samples seem to be dispersed no more widely than true replicates would be, all data on whole rock inclusions were arbitrarily combined (weighted) as six set means to obtain a single 'mean inclusion' value for each ratio. These results are also shown in Table 2.

Mineral separates from Allende inclusions: mineral separates are the most fertile ground for isotopic anomalies for several elements. A pyroxene separate from an Allende inclusion (USNM3529, 32 described in ref. 29) was run in duplicate samples in the usual manner. The mean results are shown in Table 2. Uncertainties quoted are based on the observed dispersion of these true replicates and are similar to the others quoted.

Allende material with oxygen anomalies: some inclusion whole rock and density separates from Allende in which oxygen anomalies had been found were processed for titanium in the usual manner. As three of the samples (all mostly pyroxene from Al 6S3 and Al 3S4) have virtually identical oxygen anomalies³⁰ and because each of the individual samples seems to be anomalous in titanium (see Table 3) and because the normalised individual sample mean data points fall within the area inferred to exist for replicate results, the results for these samples, including one chemically reprocessed sample, have been combined to provide the mean values shown in Table 2. As usual, the quoted uncertainties are computed from the dispersion of the individual sample values.

Discussion

The data represented by the values shown in Table 2 have been carefully considered and, in particular, all apparent deviations from the terrestrial values have been tested for significance using the *t*-test. If 47/49 is assumed to be the same in all materials measured, the results of this study of titanium isotope ratios show that, within the limits of the relevant experimental precisions: (1) terrestrial materials from four different sources

display the same values with a mean relative three sigma of the mean uncertainty of about 0.03%; (2) Allende whole rock is not distinguishable from mean terrestrial material; (3) the chemical leaches from Allende whole rock, while showing some variations, do not differ significantly (three sigma level) from mean terrestrial material in their means; (4) results on inclusions and on a mineral separate extracted from an inclusion scatter in a manner consistent with the precision observed for the replication of other materials and with mean values within 0.1% (and not different from at the three sigma level) the mean terrestrial values for all ratios. However, note that arbitrary combination of all inclusion values would tend to dilute the effect of any anomalous material which might be present in only one or some of the inclusions or fractions thereof. Therefore, (5) if only inclusion material with documented oxygen anomalies is considered, the frequency distribution of individual 50/49 set means is found to be displaced from that for terrestrial materials, as shown in Table 4, and the mean 50/49 is found to be significantly (greater than three sigma of the mean) higher than for the mean terrestrial material. The observed *t* is 3.95, which for eight degrees of freedom represents about four chances in 1,000 that both the terrestrial and oxygen-anomalous sample means represent individual results drawn from a single normal frequency distribution. This is highly unlikely and we conclude that these meteoritic materials are different from terrestrial materials in their titanium isotopic composition to an extent comparable with recently reported anomalies in other elements in Allende^{8,11}.

Although the statistical analyses described above confirm a significant difference between the isotopic ratios in question, they cannot be used to exclude the presence of any of several possible systematic errors which might cause such a difference. We have carefully considered all such possibilities. For example, the origin of this observed enhancement of the 50/49 ratio in these inclusions cannot be single-stage Rayleigh mass fractionation because the process of normalisation would, of course, eliminate or at least obscure any pre-laboratory physicochemical mass fractionation such as has been observed for other elements, as well as that introduced by the mass-spectrometric measurement procedures. However, any normalisation can also distort the nature and extent of any nucleogenic anomalies present. The effects of such alternate normalisations have been extensively investigated and found to provide results consistent with expectations as to their nature and magnitude but of poorer precision due to the additional extrapolations and interpolations required vis-a-vis the 47/49 normalisation. Therefore, in the absence of evidence to the contrary, we prefer to use the latter.

Thus, either a depletion of ⁴⁹Ti or an enhancement in ⁵⁰Ti abundance is required. Ockham's Razor can be applied to argue against the former in that simultaneous appropriate depletions in the other three titanium isotope abundances would be required to maintain the agreement with terrestrial values obtained for the other ratios. Therefore, an enhancement at mass 50 is indicated. As described above, mass scans allowed the rejection of data where questionable peak shapes or baselines were present and corrections for known nuclidic isobars present during each set were made, with no systematic trends evident.

Table 3 Magnitudes of isotopic ratio anomalies

Allende inclusion*	Relative magnitudes (p.p.t.) of anomaly in isotopic ratio					
	¹⁷ O/ ¹⁶ O*	¹⁸ O/ ¹⁶ O*	²⁶ Mg/ ²⁴ Mg†	²⁹ Si/ ²⁸ Si‡	³⁰ Si/ ²⁸ Si‡	⁵⁰ Ti/ ⁴⁹ Ti§
Al 3S4	-39.3	-38.0	0.3 to 135	-0.3	1.8	1.2 ± 0.9
Al 6S3	-38.8	-36.6	—	—	—	1.2 ± 0.9
						2.0 ± 1.2
						Average = 1.4 ± 0.7

† Normalised to (47/49) = 1.3360.

Therefore, in the absence of any evidence of unusual conditions during the measurement of any of the three anomalous samples, we conclude that the ^{50}Ti abundance is higher than normal in these oxygen anomaly-bearing inclusions.

The coincidence of anomalies in different elements in the same material suggests a common origin in a nucleosynthetic history for some fraction of the material that is distinct from the history for most of the materials studied. In attempting to account for the normal nuclide abundance pattern, various workers have modelled both hydrostatic and explosive thermonuclear processes. Despite great uncertainties in both the nuclear physical and the astrophysical input information, considerable success has been achieved. Such calculations^{31–33} indicate that explosive carbon burning can result in matter which is simultaneously enriched in ^{16}O , ^{26}Mg , and ^{50}Ti , just the coincidences reported in this work and previously^{30,35}, as shown in Table 3.

The picture concerning the magnitude and variety of isotopic anomalies is far from complete³⁷. Therefore, it seems that

additional studies of the correlation of anomalies in different elements must be undertaken. In particular, in the case of titanium, the existence and locus of a true anomaly (rather than a highly improbable statistical fluctuation or an undetected systematic error) must be independently confirmed, and the anomaly-carrying phase(s) must be identified. These are tasks for which the high resolution ion microprobe may be particularly well suited.

In conclusion, the results of this study indicate that a nucleogenic anomaly in titanium, most probably an enrichment in ^{50}Ti abundance, exists in some oxygen-anomaly bearing Allende inclusions.

We thank J. R. deLaeter for encouraging us to study Ti isotopes and R. N. Clayton, E. Jarosewich, B. Mason, T. K. Mayeda and S. R. Taylor for providing valuable documental materials. H.R.H. received financial support in the form of a Visiting Fellowship from the Australian National University and of a sabbatical leave from Purdue University.

Volcanic eruption through a geothermal borehole at Námafjall, Iceland

Gudrún Larsen & Karl Grönvold

Nordic Volcanological Institute, University of Iceland

Sigurdur Thorarinnsson

Science Institute, University of Iceland, Reykjavik, Iceland

During the present rifting episode in the Krafla fault swarm in North Iceland, large scale horizontal movement of basaltic magma is taking place underground. On 8 September 1977 magma reached the depth range of boreholes in the Námafjall geothermal field. In 20 min 3 ton of magma erupted through an 1,138 m borehole forming a small scoria sheet.

THE eruption on 8 September 1977 in the Námafjall geothermal field was a part of a rifting event that took place during that day, and which itself is a part of a major rifting episode which has been in progress on the Krafla fault swarm in North Iceland since 20 December 1975^{1–4}. The eruption through the borehole provides further evidence for a large scale magma movement along the fault swarm initially postulated from ground deformation observations⁵.

The Krafla fault swarm is ~100 km long, and about 70 km

Fig. 1 The main geological features of the Krafla area and location of the eruptions 1975-77. The Námafjall area is shown in greater detail in Fig. 2. Adapted from a map by Kristján Saemundsson¹.

have been activated with horizontal widening of 2-3 m in places. Magma is being continuously fed (about $5 \text{ m}^3 \text{ s}^{-1}$) into magma reservoirs below the Krafla caldera (Fig. 1) at a depth of about 3 km, as indicated by seismic and ground deformation evidence¹.

The rifting activity takes place in short events where 5-15 km long segments of the fault swarm are activated with movements on faults, earthquakes and the formation of new steam fields. This is accompanied by subsidence of a large area with a centre within the Krafla caldera caused by magma movement into the fault swarm.

Three small lava eruptions have accompanied the eight rifting events that have taken place, but all three eruptions were in the vicinity of the magma reservoirs and so far only the eruption through the borehole has provided samples of the magma actually moved into the fault swarm.

The total volume of magma moved into the fault swarm is about $3.9 \times 10^8 \text{ m}^3$, while the volume of the lavas is about $2.4 \times 10^6 \text{ m}^3$ or 0.6%.

The first eruption, on 20 December 1975, took place near the centre of the caldera (Fig. 1) although the main rifting occurred 45 km to the north. The second eruption, on 27 April 1977, took place near the northern rim of the caldera (Fig. 1), while the main rifting occurred about 10 km to the south of the caldera centre.

In the third eruption, on 8 September 1977, the main outflow of lava was again near the northern rim of the caldera, while the

main rifting took place south of the caldera, just north of the Námafjall geothermal field. We give here a short account of this event and the borehole eruption.

8 September deflation/rifting event

The deflation and rifting of 8 September 1977 started with a volcanic tremor recorded on seismographs at 15.47 h and about the same time the centre of the caldera started deflating. Just before 18.00 h a lava eruption started near the northern rim of the Krafla caldera (Fig. 1). According to the pilots of an overflying aeroplane, its first sign was a white column of steam darkening at the base after a few minutes. Shortly afterwards lava spattering started from a short segment of the fissure, which rapidly extended to a total length of 800 m. The lava output increased quickly, reaching maximum in less than about 30 min, and by 19.30 h most of the lava was already erupted. By 22.30 h the activity had died out. Assuming that the magma started to ascend when volcanic tremor appeared on the seismometers and deflation on the tiltmeter, the rate of ascent is about 0.5 m s^{-1} assuming a depth of 3 km for the magma reservoirs.
